Short title: Identification of a B$_{12}$ uptake protein in algae

One sentence summary: Knockout mutants and physiological studies demonstrate that vitamin B$_{12}$ uptake in both *Chlamydomonas reinhardtii* and the unrelated *Phaeodactylum tricornutum* requires cobalamin acquisition protein 1.

Keywords: cobalamin, *Chlamydomonas reinhardtii*, *Phaeodactylum tricornutum*, insertional mutagenesis, CLiP mutants, CRISPR-Cas9, riboswitch

Manuscript length: 7241 words
Abstract

Microalgae play an essential role in global net primary productivity and global biogeochemical cycling. Despite their phototrophic lifestyle, over half of algal species depend for growth on acquiring an external supply of the corrinoid vitamin B\textsubscript{12} (cobalamin), a micronutrient produced only by a subset of prokaryotic organisms. Previous studies have identified protein components involved in vitamin B\textsubscript{12} uptake in bacterial species and humans. However, little is known about its uptake in algae. Here, we demonstrate the essential role of a protein, cobalamin acquisition protein 1 (CBA1), in B\textsubscript{12} uptake in Phaeodactylum tricornutum using CRISPR-Cas9 to generate targeted knockouts and in Chlamydomonas reinhardtii by insertional mutagenesis. In both cases, CBA1 knockout lines could not take up exogenous vitamin B\textsubscript{12}. Complementation of the C. reinhardtii mutants with the wild-type CBA1 gene restored B\textsubscript{12} uptake, and regulation of CBA1 expression via a riboswitch element enabled control of the phenotype. When visualised by confocal microscopy, a YFP-fusion with C. reinhardtii CBA1 showed association with membranes. Bioinformatics analysis found that CBA1-like sequences are present in all major eukaryotic phyla. In algal taxa, the majority that encoded CBA1 also had genes for B\textsubscript{12}-dependent enzymes, suggesting CBA1 plays a conserved role. Our results thus provide insight into the molecular basis of algal B\textsubscript{12} acquisition, a process that likely underpins many interactions in aquatic microbial communities.
INTRODUCTION

Microalgae are a diverse group of eukaryotic organisms that thrive in all aquatic environments. They form the basis of most aquatic food chains and are major contributors to global primary productivity, with marine microalgae responsible for an estimated 30% of total carbon fixation (Field et al., 1998). Understanding the drivers that support algal growth is thus of considerable ecological importance. Despite their photoautotrophic lifestyle, a widespread trait in algae is dependence on an external source of an organic micronutrient, vitamin B\textsubscript{12} (cobalamin), a complex cobalt-containing corrinoid molecule. Approximately half of algal species surveyed across the eukaryotic tree of life require B\textsubscript{12} for growth (Croft et al., 2005). However, the proportion of B\textsubscript{12}-dependent species differs between algal groups, from 30% (n=148) of Chlorophytes to 96% (n=27) of algal species that participate in harmful algal blooms (Tang et al., 2010). Within algal lineages, there is no evidence that any can produce B\textsubscript{12} \textit{de novo}, so this auxotrophy is not due to loss of one or more biosynthetic genes. Rather, the requirement for B\textsubscript{12} stems from the fact that it is an essential cofactor for methionine synthase (METH), and species that can grow without supplementation have an alternative, B\textsubscript{12}-independent, isoform of this enzyme called METE (Croft et al., 2005; Helliwell et al., 2011). Many microalgae, including the green alga \textit{Chlamydomonas reinhardtii} and the unrelated diatom \textit{Phaeodactylum tricornutum}, encode both forms of methionine synthase and utilise METE in the absence of exogenous B\textsubscript{12}, but take up and utilise the compound if it becomes available (Helliwell et al., 2011). Under those conditions, the expression of METE, which has been found to have a lower catalytic rate than METH (Gonzalez et al. 1992), is repressed, and cells rely on METH activity.

The biosynthetic pathway for B\textsubscript{12} is confined to prokaryotes (Warren et al., 2002) and indeed only a subset of bacteria encode the entire set of 20 or so enzymes required to synthesise corrinoids from the common tetrapyrrole precursor (Shelton et al., 2019), with many eubacterial species also reliant on an external source. In some cases, this is due to the loss of one or a few enzymes of the biosynthetic pathway, but in many bacteria the pathway is absent altogether and auxotrophy is the consequence of relying on one or more B\textsubscript{12}-dependent enzymes, such as METH. In microalgae, supplementation of cultures of \textit{P. tricornutum} with B\textsubscript{12} increases its growth rate subtly (Bertrand et al., 2012) and in C.
reinhardtii use of METH confers thermal tolerance (Xie et al., 2013). More direct evidence for a selective advantage is demonstrated by the fact that an experimentally-evolved metE mutant of C. reinhardtii predominates in mixed populations with wild-type cells over tens of cell generations, as long as B12 is included in the medium (Helliwell et al., 2015). This is despite the fact that in the absence of B12, the metE mutant is non-viable within a few days (Bunbury et al., 2020).

The minimum levels of B12 in the medium needed to support growth of laboratory cultures of algal B12-auxotrophs are in the range of 10-50 pM (Croft et al., 2005), whereas B12 concentrations have been reported to be just 5-13 pM in freshwater systems (Ohwada, 1973). A similar value of 6.2 pM is the average value in most marine environments, although up to 87 pM could be detected in some coastal waters (Sañudo-Wilhelmy et al., 2014), which may be linked to the higher cobalt concentrations measured there (Panzeca et al., 2009). Given the limiting levels of B12 in the environment, its relatively short half-life (in the order of days) in surface water (Carlucci et al., 2007; Sañudo-Wilhelmy et al., 2014), and that as a large polar molecule it is unlikely to simply diffuse across cellular membranes, it is clear that algae must have an efficient means to take up B12. In bacteria, the molecular mechanisms for B12 uptake have been extensively characterised. The B12 transport and utilisation (btu) operon is perhaps the best known (Kadner, 1990), comprising BtuB, a TonB-dependent transporter in the outer membrane, a B12-binding protein, BtuF, located in the periplasm, and BtuC and BtuD, components of an ATP-binding cassette (ABC) transporter that sits in the inner membrane (Borths et al., 2002). In mammals, dietary B12 is bound to intrinsic factor in the ileum and taken up from the gut via receptor-mediated endocytosis (Nielsen et al., 2012). It is then transported between and within cells via multiple B12 transport proteins (Banerjee et al., 2021; Choi and Ford, 2021). These include lipocalin-1 interacting membrane receptor domain-containing protein 1 (LMBD1), ATP-binding cassette subfamily D member 4 (ABCD4), the latter being an integral membrane ABC transporter in the lysosomal membrane of gut epithelial cells, which facilitates delivery of B12 into the cytosol, and multidrug resistant protein 1 (MRP1, also known as ABCC1), another ABC transporter that has sequence similarity to BtuCD and is involved in export of free B12 into the plasma where it binds to the main B12 transport protein, transcobalamin (Beedholm-Ebsen et
Mice *mrp1* mutants were still able to transport a small amount of cobalamin out of cells, indicating redundant mechanisms for this function that have not yet been identified. Cobalamin circulating in the plasma bound to transcobalamin can then be taken up by other cells via receptor-mediated endocytosis (Nielsen et al., 2012).

In contrast to these well-studied processes in bacteria and mammals, the understanding of B$_{12}$ acquisition in microalgae is more limited. A survey of microalgal species, including marine and freshwater taxa and those that require B$_{12}$ (for example *Euglena gracilis*, *Thalassiosira pseudonana*), and non-requirers (such as *P. tricornutum*, *Dunaliella primolecta*), found that many released a ‘B$_{12}$-binder’ into the medium, likely a protein, that appeared to sequester B$_{12}$ from solution and thereby inhibited growth of B$_{12}$-dependent algae (Pintner and Altmeyer, 1979). Its role was unknown, but it was postulated that it might be involved in competition for resources between microalgal species in the environment. Subsequently, a protein was purified from the medium of cultures of *T. pseudonana* with a high affinity binding constant of 2 pM for B$_{12}$ (Sahni et al., 2001). In its native state it was an oligomer of >400 kDa, with subunits of ~80 kDa and the amino acid profile was determined, but it was not possible to obtain sufficient amounts to characterise further. A different approach was taken by Bertrand et al. (2012), who conducted a transcriptomics and proteomics study of *P. tricornutum* and *T. pseudonana* grown under low or sufficient B$_{12}$ conditions. This led to the identification of a gene highly upregulated at the transcript and protein level in the absence of B$_{12}$. Overexpression of this protein in *P. tricornutum* resulted in an increase in the rate of B$_{12}$ uptake, and the protein was named CoBalamin Acquisition protein 1 (CBA1) although no direct role was established. In this study we have taken a mutagenesis approach to identify genes responsible for B$_{12}$ uptake in both *P. tricornutum* and *C. reinhardtii*, including extending the work on CBA1. In addition, we have determined the extent to which candidate proteins are conserved throughout the algal lineages, making use of recent increases in algal sequencing data.
RESULTS

*P. tricornutum CBA1* knockout lines do not take up B<sub>12</sub>

Previous work showed that overexpression of CBA1 in *P. tricornutum* conferred enhanced B<sub>12</sub> uptake rates (Bertrand et al., 2012) but the study did not demonstrate whether it was essential for this process. To address this question, *CBA1* knockout lines were generated in *P. tricornutum* strain 1055/1 (Supplemental Table S1) by CRISPR-Cas9 editing, using a homologous recombination repair template that included a nourseothricin resistance (*NAT*) cassette (Figure 1a). CRISPR-Cas9 lines were cultured on selective media and screened for the absence of WT alleles at the *PtCBA1* locus (Phatr3_J48322) using PCR (Figure 1b). When the *PtCBA1* gene was amplified (top panel, Figure 1b) from ∆CBA1-1 with primers flanking the homologous recombination regions, two bands were detected; the larger of these corresponded to the WT amplicon, whilst the smaller band corresponded to a replacement of *CBA1* by *NAT*, suggesting that this strain is a mono-allelic knockout. For ∆CBA1-2, the *PtCBA1* gene primers amplified a single smaller product, suggesting that this was a bi-allelic knockout, whereas the *PtCBA1* ORF primers (bottom panel of Figure 1b) did not amplify anything, indicating a disruption specifically in this region. Similarly, no band was detected with primers that amplify across the 5’ end of the NAT knock-in (HR primers), which might indicate further disruptions upstream of the 5’HR region of ∆CBA1-2. Although a larger band than for WT was amplified in ∆CBA1-3 using the *PtCBA1* gene primers, those for the *PtCBA1* ORF amplified a smaller product; in both cases a single band was observed indicating a bi-allelic deletion at the sgRNA target sites.

To test whether the ∆CBA1 lines were affected in their ability to take up vitamin B<sub>12</sub> we developed a standardised B<sub>12</sub>-uptake assay, detailed in Materials and Methods. In brief, algal cells were grown to the same growth stage and adjusted to the same cell density, then incubated in media containing a known amount of cyanocobalamin for one hour. Thereafter, cells were pelleted by centrifugation and the amount of B<sub>12</sub> determined in the cell pellet and the media fraction using a *Salmonella typhimurium* bioassay (Bunbury et al., 2020). For each sample, the B<sub>12</sub> measured in the cellular and media fractions were added to provide an estimated ‘Total’ and compared to the amount of B<sub>12</sub> added initially (Figure...
To determine the extent of recovery. For the WT strain, most of the added B\textsubscript{12} was found in the cellular fraction. The mono-allelic knockout line \(\Delta CBA1\) consistently showed ~20-30\% \(B\textsubscript{12}\) uptake relative to the WT strain. This suggested that a single copy of \(PtCBA1\) is sufficient to confer \(B\textsubscript{12}\) uptake in \textit{P. tricornutum}, but not to the same extent as the WT strain. In contrast, for the two bi-allelic knockout lines (\(\Delta CBA1\)-2 and \(\Delta CBA1\)-3) no \(B\textsubscript{12}\) was detected in the cellular fraction in any experiment, indicating that vitamin \(B\textsubscript{12}\) uptake was fully impaired in the absence of a functional \(PtCBA1\) copy, at least at the limit of detection of the \(B\textsubscript{12}\) bioassay (of the order of 10 pg). These results expand our understanding of \(PtCBA1\) by demonstrating that its presence is essential for \(B\textsubscript{12}\) uptake and indicates that there is no functional redundancy to \(PtCBA1\).

**Insertional mutagenesis identified the \textit{C. reinhardtii} homologue of \textit{CBA1}**

Bertrand et al. (2012) reported that there were no detectable \textit{CBA1} homologues in algal lineages outside the Stramenopiles, so to investigate \(B\textsubscript{12}\) uptake in \textit{C. reinhardtii}, we decided to take an insertional mutagenesis approach. We took advantage of the fact that \(B\textsubscript{12}\) represses expression of the \textit{METE} gene at the transcriptional level via the promoter (\(P\textsubscript{METE}\)), and that reporter genes driven by this genetic element respond similarly (Helliwell et al., 2014), to develop a highly sensitive screen for lines no longer able to respond to \(B\textsubscript{12}\). We hypothesised that, since \(P\textsubscript{METE}\) is likely to respond specifically to intracellular \(B\textsubscript{12}\), \(P\textsubscript{METE}\) would not be repressed in strains unable to take up \(B\textsubscript{12}\) from the media, so the reporter would be expressed and functional. If the reporter were an antibiotic resistance gene, this would allow identification of \(B\textsubscript{12}\) uptake mutants in a more high-throughput manner than the \(B\textsubscript{12}\)-uptake assay. The background strain for insertional mutagenesis was made by transforming \textit{C. reinhardtii} strain UVM4 (Neupert et al., 2009) with plasmid pAS\_R1 containing a paromomycin resistance gene (\textit{aphVIII}) under control of \(P\textsubscript{METE}\) (Figure 2a, top construct; Supplemental Table S2). Lines of this strain were tested for their responsiveness to \(B\textsubscript{12}\) and paromomycin. One line, UVM4-T12, showed the appropriate sensitivity with increasing repression of growth in paromomycin as \(B\textsubscript{12}\) concentrations were increased, the effect being more marked at 15-20 \(\mu\text{g}\cdot\text{ml}^{-1}\) paromomycin than at 5-10 \(\mu\text{g}\cdot\text{ml}^{-1}\) (Figure 2b). This line thus allowed for an easily quantifiable growth phenotype that was proportionally related to \(B\textsubscript{12}\) concentration.
Insertional mutagenesis was carried out by transforming UVM4-T12 with a plasmid (pHyg3) containing a hygromycin resistance gene (aphVII) under the control of the constitutively expressed β2-tubulin promoter (Figure 2a, bottom construct), generating a population of UVM4-T12::pHyg3 lines with the cassette randomly inserted into the nuclear genome. By plating the products of the transformation on solid TAP media supplemented with a range of paromomycin, hygromycin and vitamin B₁₂ concentrations (see Methods), 7 colonies were obtained. This was estimated to be from approximately 5000 primary transformants, determined by plating the same volume on TAP plates with the antibiotics but without B₁₂. These 7 putative insertional mutant (IM) lines were then assessed for their ability to take up B₁₂ using the B₁₂ uptake assay. For UVM4, UVM4-T12 and insertional lines from the plate without B₁₂ (labelled Control 1-3), similar amounts of B₁₂ were recovered from the cellular and media fractions (Supplemental Figure S1). This was also the case for 6 of the IM lines, suggesting that they could still take up B₁₂ and were likely false positives of the initial screen. However, no B₁₂ could be detected in the cellular fraction of UVM4-T12::pHyg3 #IM4 (hereafter referred to as IM4), indicating that this mutant line did not take up B₁₂.

To obtain independent corroboration that IM4 was impaired in B₁₂ uptake, cells of this mutagenized line were incubated with a fluorescently-labelled B₁₂ derivative, B₁₂-BODIPY (Lawrence et al., 2018), and then imaged using confocal microscopy. C. reinhardtii cells were incubated in TAP medium without B₁₂-BODIPY or with 1 µM B₁₂-BODIPY for 1 hour, washed with fresh media and subsequently imaged. There was no signal detected in the channel used for B₁₂-BODIPY (589 nm excitation; 607-620 nm detection) in samples without B₁₂-BODIPY added (Supplemental Figure S2, top two rows), indicating that the imaging protocol was specific to this compound. When B₁₂-BODIPY was added, UVM4-T12 showed the B₁₂-BODIPY signal located within the algal cell (Supplemental Figure S2, third row), indicating that this signal could be effectively detected by the imaging protocol and that B₁₂-BODIPY was being transported into the cells. In contrast, there was no B₁₂-BODIPY signal in IM4 cells, supporting the hypothesis that B₁₂ uptake was impaired in this mutant (Supplemental Figure S2, bottom row). In addition, the response of the METE gene to B₁₂ in
IM4 was assessed by RT-qPCR. UVM4 and IM4 cultures were grown in media with or without addition of B$_{12}$ for 4 days in continuous light, after which the cultures were harvested for RNA extraction and cDNA synthesis. As expected, METE was repressed in UVM4 in the presence of B$_{12}$ compared to no supplementation (Figure 3a), whereas IM4 showed similar METE expression in both conditions. This provided further support for disrupted B$_{12}$ uptake in this line.

To identify the genomic location of the causal mutation in IM4, short-read whole genome sequencing was performed on DNA samples from UVM4, UVM4-T12 and IM4. The location of the pHyg3 cassette in IM4 was identified as described in Methods and found to have disrupted the Cre12.g508644 locus (Supplemental Figure S3a), an unannotated gene. To corroborate that disruption of the Cre12.g508644 was responsible for the uptake-phenotype, two independent mutant lines of the gene (LMJ-119922 and LMJ-042227) were ordered from the Chlamydomonas library project (CLiP) collection (Li et al., 2016) and verified to be disrupted at this locus by PCR (Supplemental Figure S3a). However, when these knockout lines were tested for the ability to take up B$_{12}$ using the B$_{12}$ uptake assay, they were both found to be able to do so to a similar extent as their parental strain, cw15 (Figure S3b). This suggested that Cre12.g508644 did not encode a protein essential for B$_{12}$ uptake.

We therefore examined the genome sequence data more closely to determine the genetic cause for the B$_{12}$-uptake phenotype of IM4. We had identified putative homologues of human proteins involved in receptor-mediated endocytosis of B$_{12}$, such as ABCD4, LMBD1 (Rutsch et al., 2009; Coelho et al., 2012) and MRP1 (Beedholm-Ebsen et al., 2010), in the C. reinhardtii genome by BLAST. However, given the widespread percentage of SNPs in the IM4 genome compared to UVM4, it was not possible to identify any candidate causal mutations with confidence. Instead, manual inspection of the DNA sequencing reads mapped to the reference strain revealed one locus, Cre02.g081050, annotated as flagella-associated protein 24 (FAP24), where there was a unique discontinuity, suggesting that there was an insertion at exon 2 in IM4 (Figure 3b; Supplemental Figure S4a). The sequence was bordered by a genome duplication of 8 bp (shown in blue in Figure S4a) and exhibited imperfect inverted repeats at the terminal regions (TIRs), indicative of a transposable element. Reads could not be
assembled across the discontinuity to obtain the complete sequence of the insertion, but using the left
and right junction sequences as queries, three regions encoding two very similar genes were identified
(Supplemental Figure S4b).

Remarkably, when the Cre02.g081050 protein was used as a query in a BLAST search, one of the hits
recovered was the PtCBA1 protein (22.9% sequence identity), even though the reciprocal sequence
search had not picked up the C. reinhardtii gene (Bertrand et al., 2012). Predicted 3D structures of
PtCBA1 and the C. reinhardtii protein encoded by Cre02.g081050 were obtained from the
AlphaFold2 protein structure database and overlaid (Supplemental Figure S5). The modelled proteins
showed a high degree of structural similarity to one another (root mean squared deviation (RMSD) =
1.688), particularly with respect to the arrangement of alpha helices and a lower cleft. Due to the
sequence similarity and predicted structural similarity, these proteins appeared to be homologous to
one another and Cre02.g081050 is hereafter referred to as CrCBA1.

To determine whether disruption of CrCBA1 in IM4 was responsible for the impaired B12 uptake, we
investigated whether it was possible to restore its ability to take up B12 by transforming IM4 with the
wild-type CrCBA1. Construct pAS_C2 was designed with the CrCBA1 promoter, CrCBA1 open
reading frame (ORF) and terminator and included a 3’ mVenus tag attached by a poly-glycine linker
(Figure 3c). IM4 was transformed with pAS_C2, and resulting lines were tested for the ability to take
up B12 using the B12 uptake assay. As observed previously, UVM4 was able to take up B12 whilst IM4
was unable to do so (Figure 3d). The CBA1 complementation line IM4::pAS_C2 showed B12 in the
cellular fraction at similar levels as in UVM4, thereby indicating that the mutant phenotype had been
complemented.

CrCBA1 CLiP mutant is unable to take up B12 and is complemented by the WT CrCBA1 gene

Given the many genetic changes in line IM4 compared to the parental UVM4-T12 strain caused by
the mutagenesis, it was essential to have independent corroboration that mutation of CrCBA1 caused
the inability to take up B12. Accordingly, we obtained two further CLiP mutants (LMJ-135929 and
LMJ-040682) with disruptions in intron 2 and introns 6/7 respectively of CrCBA1 (Supplemental Figure S6a) and assessed them for their ability to take up B$_{12}$ (Supplemental Figure S6b). No B$_{12}$ was detected in cells of LMJ-040682, indicating complete inhibition of B$_{12}$ uptake. Although LMJ-135929 cells accumulated some B$_{12}$, this was less than half the amount of its parent strain cw15, suggesting partial impairment in uptake, similar to the phenotype of the monoallelic PtCBA1 knockout line (Figure 1c). However, heterozygosity cannot be the explanation for C. reinhardtii, which is haploid, and instead indicates that LMJ-135929 was likely to have just partial knockdown of the gene, probably because the insertion is in an intron.

Nonetheless, to provide further confirmation that mutations in CrCBA1 were responsible for the observed impaired B$_{12}$ uptake, we again tested whether the phenotype could be complemented with the wild-type CrCBA1 gene using both plasmid pAS_C2 (Figure 3b) and an additional construct pAS_C3 (Figure 4a), in which expression of CrCBA1 can be controlled by a thiamine pyrophosphate (TPP) repressible riboswitch, RS$_{THI4_{4N}}$ (Mehrshahi et al., 2020). In the absence of thiamine supplementation of the cultures, the riboswitch is not active and the gene containing it is transcribed and translated as normal; with thiamine addition, alternative splice sites are utilised, leading to inclusion of an upstream ORF containing a stop codon in the mRNA, preventing translation from the downstream start codon. LMJ-040682 was transformed with both pAS_C2 and pAS_C3, and representative transformant lines selected via antibiotic resistance were obtained. These, together with their parental strains were grown in the presence or absence of 10 µM thiamine for 5 days, and then used in the B$_{12}$ uptake assay. Transformants of both LMJ-040682::pAS_C2 and LMJ-040682::pAS_C3 were found to take up B$_{12}$ to a similar extent as their parental strain cw15 when grown in the absence of thiamine (Figure 4b). However, when 10 µM thiamine was included in the culture medium, LMJ-040682::pAS_C3 showed virtually no B$_{12}$ uptake. This riboswitch-mediated conditional complementation of the phenotype in LMJ-040682::pAS_C3 demonstrated conclusively that B$_{12}$ uptake in C. reinhardtii is dependent on the presence of CrCBA1.
CrCBA1 shows an association with membranes and is highly upregulated under B\textsubscript{12}-deprivation

To investigate the subcellular location of CrCBA1, we used several bioinformatic targeting prediction tools. CrCBA1 is annotated as a flagella-associated protein in the Phytozome v5.6 C. reinhardtii annotation. However, both DeepLoc (Almagro Armenteros et al., 2017) and SignalP (Almagro Armenteros et al., 2019), as well as AlphaFold2, indicated a hydrophobic sequence with the characteristics of a signal peptide at the N-terminus of CrCBA1 and predicted it would be targeted to the endoplasmic reticulum (ER). Additionally, it was predicted to contain a transmembrane helix at its C-terminus by InterPro (Mitchell et al., 2019) and AlphaFold2.

We next investigated the subcellular location of CrCBA1 in vivo by imaging two lines of LMJ-040682::pAS_C2, where the CBA1 is tagged with mVenus, with confocal microscopy. No mVenus was detected in the parental LMJ-040682 cells, whereas a clear fluorescent signal was observed in LMJ-040682::pAS_C2 #A10 and LMJ-040682::pAS_C2 #D10 (Figure 5). In these complemented lines, the mVenus signal was absent from the chloroplast, nucleus and flagella, but instead could be seen within the cell localising both to the plasma membrane and to regions that may be endomembranes such as the ER. This is consistent with findings from P. tricornutum showing a similar distribution (Bertrand et al., 2012). Together these data indicate that CBA1 is likely to be associated with membranes, and therefore, may have a conserved role in the B\textsubscript{12} uptake process.

Further evidence for the role of CBA1 in B\textsubscript{12} uptake was obtained by taking advantage of a B\textsubscript{12}-dependent mutant of C. reinhardtii, metE7 (Helliwell et al., 2015; Bunbury et al., 2020). We tested the effect of B\textsubscript{12}-deprivation over time on the expression of the CrCBA1 gene by RT-qPCR in the mutant and determined the rate of B\textsubscript{12} uptake over a similar period. Within 6h of B\textsubscript{12} removal, there was a ~250-fold induction of the CrCBA1 transcript, followed by a slow decline over the next 60h (Figure 6a). After resupply of B\textsubscript{12} there was then a rapid ~100-fold decline within 8h. The B\textsubscript{12} uptake capacity of metE7 followed a similar profile, increasing 3-fold over the first 12 hours of B\textsubscript{12} depletion,
from \(-6.5 \times 10^5\) molecules B\(_{12}\)/cell/hour to \(1.86 \times 10^6\) molecules B\(_{12}\)/cell/hour (Figure 6b), then declining slowly. This induction profile is characteristic of a nutrient-starvation response shown by many transporters, including in \(C.\) reinhardtii those for Fe (Allen et al., 2007), and for \(CBA1\) in the \(B_{12}\)-dependent diatom, \(Thalassiosira\) pseudonana (Bertrand et al., 2012).

**Widespread distribution of CBA1 in algae**

Having shown the importance of \(PtCBA1\) and \(CrCBA1\) for B\(_{12}\) uptake in their respective species, we re-examined how prevalent CBA1-like proteins are in Nature. Searches with BLASTP using \(PtCBA1\) were reported to result in no significant hits in species outside the Stramenopiles (Bertrand et al., 2012). Instead, we created a hidden Markov model (HMM), using the \(C.\) reinhardtii CBA1 amino acid sequence and CBA1 sequences from \(P.\) tricornutum, \(T.\) pseudonana, \(Fragilariopsis\) cylindrus, \(Aureococcus\) anophagefferens and \(Ectocarpus\) siliculosus (Bertrand et al., 2012), to identify more accurately CBA1-like proteins in other organisms. The EukProt database of curated eukaryotic genomes (Richter et al. 2022) includes representatives from the Archaeplastida (designated by EukProt as Chloroplastida), which encompass green algae, red algae, glaucophytes and all land plants, as well as phyla that include algae with complex plastids, namely Stramenopiles (which include diatoms), Alveolata (including dinoflagellates), Rhizaria and Haptophyta, and the animals (both Metazoa and the Choanoflagellates, the closest living relatives of the animals), the fungi and Amoebozoa. This database was queried with the CBA1 HMM model, using a cutoff e-value of 1e-20, and 277 hits were obtained (Supplemental Figure S7; Supplemental Table S4). No candidates were found in the Metazoa, but CBA1 homologues were identified in all other phyla, including all photosynthetic groups, fungi and amoebozoa and in choanoflagellates, unicellular and colonial flagellated organisms considered to be the closest living relatives of animals (King et al., 2008).

Given that vascular plants have no B\(_{12}\)-dependent enzymes, the presence of a putative B\(_{12}\)-binding protein in several angiosperms, both monocot and dicot, and the gymnosperm \(Ginkgo\) biloba, was somewhat surprising. To address this conundrum, we investigated to what extent CBA1 was associated with vitamin B\(_{12}\) dependence by determining the distribution of the different isoforms of
methionine synthase, METH and METE. Using the same HMM approach as before, the protein sequences were searched against the EukProt database and the combination of presence and absence of CBA1, METH and METE across eukaryotic species groups was compiled (Figure 7; Supplemental Table S5). What is immediately apparent is that the combination of the three proteins is quite different in the various lineages. In the major algal groups, the Chlorophyta and the SAR clade (Stramenopiles, Alveolata and Rhizaria), METH sequences were found in the majority of genomes analysed and their presence was associated with CBA1. In the genomes of the Chlorophyta and the SAR clade that encoded METE only (7 taxa in total), CBA1 was absent in all but one, the diatom *Thalassionema nitzschiodes*. Equal numbers of Alveolata species encoded METH and CBA1, or METH only; interestingly, the latter were all non-photosynthetic lineages. Grouping the data from these 4 algal groups, a Chi Square test was significant for CBA1 and METH being more often both present or both absent ($X^2 (1, N = 86) = 9.2, p = 0.00240$). The association could be due to linkage, although in neither *C. reinhardtii* nor *P. tricornutum* are the two genes on the same chromosome, making this unlikely. Alternatively, there is a fitness advantage in both genes being acquired or lost together.

Most fungal taxa lacked both METH and CBA1, but we found examples of 6 species that were predicted to be B$_{12}$ users (METH present) and 5 of these were also predicted to contain CBA1-like sequences: *Allomyces macrogynus*, *Spizellomyces punctatus*, *Rhizophagus irregularis*, *Rhizopus delemar* and *Phycomyces blakesleeanus*. CBA1-like sequences were identified in the Opisthokonta and Amoebozoa, although were less prevalent, with ~23% of choanoflagellates and 8% of amoeboid species being like algae in having both METH and CBA1. CBA1 was entirely absent from the Metazoa. In contrast, in the Streptophyta, which include multicellular green algae and all land plants, the majority lack METH, but almost 80% of species were found to contain CBA1-like sequences. This implies that Streptophyta CBA1 sequences may have gained a different function, which would be consistent with the lack of B$_{12}$-dependent metabolism in these organisms. In summary, these data suggest that CBA1 is associated with vitamin B$_{12}$ use to different degrees in different eukaryotic groups, with there being a greater association in obligate and facultative B$_{12}$ users than in those organisms that do not utilise B$_{12}$. 
The many putative CBA1 homologues in algal lineages and their strong association with B\textsubscript{12} uptake provided an opportunity to identify conserved, and thus likely functionally important, residues. Accordingly, a multiple sequence alignment of proteins matching the CBA1 HMM query was generated (Supplemental Figure S7). Highlighted in green in the similarity matrix at the top are nine conserved regions with several almost completely conserved residues; these are shown in more detail in Figure 8a for selected taxa representing different algal groups. Further insight came from inspection of the model of the 3D structure of CrCBA1 generated by the AlphaFold2 protein structure database. The analysis showed that regions of CrCBA1 showed similarity to bacterial periplasmic binding proteins, including the B\textsubscript{12}-binding protein BtuF. A structure is available of E. coli BtuF in complex with B\textsubscript{12} (Borths et al., 2002), so we compared this to the modelled CrCBA1 structure. Although there is little sequence similarity, alignment of the two structures resulted in an RMSD of 3.362 and enabled the relative position of B\textsubscript{12} to be placed in the lower cleft of CrCBA1, shown in red in Figure 8b. Mapping of the highly conserved residues onto this structure found that four (W255, W394, F395 and E396) were in a cluster around the relative position of B\textsubscript{12}. Another cluster of highly conserved residues were located at the end of the upper alpha helix (K78, P118, L136, F214, F215, N216 and E218). Both clusters represent promising mutational targets to investigate CrCBA1 function.

**DISCUSSION**

In this study we have shown experimentally that a conserved protein, CBA1, is required for the uptake of the micronutrient B\textsubscript{12} in two taxonomically distant algae, the diatom *P. tricornutum* (Figure 1) and the chlorophyte *C. reinhardtii* (Figures 3 & 4). Strains with knockouts of the gene were unable to take up B\textsubscript{12}, demonstrating that there is no functional redundancy of this protein in either organism. As well as providing evidence that CBA1 is present outside the Stramenopiles, we found widespread occurrence of CBA1 homologues with considerable sequence conservation across eukaryotic lineages (Figures 7 and Supplemental S7). The strong association of CBA1 with the B\textsubscript{12}-dependent methionine synthase, METH, in algal lineages, provides evidence that CBA1 is a key component of the B\textsubscript{12}
uptake process in evolutionarily distinct microalgae, and the structural similarities between CBA1 and BtuF (Figure 8b) suggest it may operate as a B_{12} binding protein. The highly conserved residues identified in the algal homologues (Figure 8a) offer the means to establish which are functionally important, facilitated by the uptake assay we established.

Nonetheless, the mechanistic role of CBA1 in the process of B_{12} acquisition in algae is not yet clear. Previous physiological studies of B_{12} uptake by microalgae, such as the haptophyte Diacronema lutheri (Droop, 1968), indicated a biphasic process: firstly rapid irreversible adsorption of B_{12} to the cell exterior, followed by a slower second step of B_{12} uptake into the cell, consistent with endocytosis. CBA1 is unlikely to be associated with the binding of B_{12} in the cell wall, however. This is because the C. reinhardtii strains used in this study, UVM4 and CW15, were cell wall deficient, and therefore likely also deficient in cell wall proteins that bind B_{12}; the lack of a B_{12}-BODIPY signal from the cell surface in IM4 (Supplemental Figure S2) supports this hypothesis. Further use of this fluorescent probe offers the possibility to monitor the localisation of B_{12}-BODIPY over time to gain insights into the stages of B_{12} uptake, as has been done in other organisms (Lawrence et al., 2018). In addition, confocal microscopy of CBA1-mVenus fusion protein in C. reinhardtii (Figure 5) showed an apparent association of CrCBA1 with the plasma membrane and endomembranes, which is similar to that for ER-localised proteins (Mackinder et al., 2017). Moreover, in a proteomics study of lipid droplets (which form by budding from the ER) CBA1 was in the top 20 most abundant proteins (Goold et al., 2016). Bertrand et al. (2012) found that PtCBA1 had a signal peptide and fluorescently tagged PtCBA1 was also targeted to the ER. Nonetheless, based on its predicted 3D structure and the fact that it has at most one transmembrane helix, CBA1 does not appear to be a transporter itself. Instead, given its structural similarity to BtuF, a distinct possibility is that CBA1 is the soluble component of an ABC transporter, either at the plasma membrane or an internal membrane, and likely will interact with one or more other proteins to allow B_{12} uptake to occur, at least some of them being those involved in receptor-mediated endocytosis, as is the case for B_{12} acquisition in humans (Rutsch et al., 2009; Beedholm-Ebsen et al., 2010; Coelho et al., 2012). In this context, there are known similarities between endocytosis in C. reinhardtii and humans (Denning and Fulton, 1989; Bykov et al., 2017).
and several putative homologues have been identified by sequence similarity in the alga. Testing the B_{12} uptake capacity of mutants of these proteins would be one approach to investigate whether their roles are also conserved.

In contrast to the situation in algae, the Streptophyta live in a B_{12}-free world, neither synthesising nor utilising this cofactor. This is exemplified by the fact that in our analysis only one species, the charophyte alga *Cylindrocystis brebissonii*, encoded METH. Despite this, more than three-quarters of this group encode a CBA1 homologue (Figures 7 & S7). Since the majority of the conserved residues (Figure 8a) are also found in putative CBA1 sequences in the angiosperms such as *Arabidopsis*, including those around the potential binding pocket, it is possible that the streptophyte protein has acquired a new function that still binds a tetrapyrrole molecule. Intriguingly, the reverse is observed in the Metazoa, where METH is almost universal, but CBA1 is entirely absent. However, some Choanoflagellates and some species of fungi do appear to encode both METH and CBA1, suggesting that they utilise B_{12}, a trait recognised to occur in fungi only recently (Orlowska et al., 2021). It will be of interest therefore to test whether CBA1 is involved in B_{12} uptake in these organisms, for example by gene knockout studies.

The importance of B_{12} availability for phytoplankton productivity has been demonstrated across several marine ecosystems by amendment experiments (e.g. Bertrand et al., 2011; Koch et al., 2012; Joglar et al., 2021), where addition of B_{12} led to algal blooms and affected the composition and stability of microbial communities. The mode of acquisition of this micronutrient is thus likely to be highly conserved and subject to substantial ecological and evolutionary selection pressure to be retained. Moreover, the role of B_{12} at the cellular level may well provide a direct connection between environmental conditions and the epigenetic status of the genome: methionine synthase is the key enzyme in C1 metabolism, linking the folate and methylation cycles and thus responsible for maintaining levels of S-adenosylmethionine (SAM) the universal methyl donor (Hanson & Roje 2001; Mentch & Locasale, 2016). In this context, it is noteworthy that the knockout of CBA1 in the IM4 line was the result of insertion of a class II transposable element into the gene. This mobilization
is likely to reflect epigenetic alterations of the autonomous element, presumably as a result of cellular stress either from the antibiotic selection, or the transformation procedure, or both. Recent classification of the transposons in *C. reinhardtii* indicate that the transposon inserted into *CBA1* in IM4 is a member of the KDZ superfamily of class II TIR elements named Kyakuja-3_cRei (Craig et al. 2021). If the phenomenon of inactivation of a gene that is deleterious (in this case allowing B_{12} to be taken up and repress the antibiotic resistance gene) via transposition is a general response in *C. reinhardtii*, repeating the screen for CBA1 mutants might allow observation of further transposition events, and enable characterisation of this group of elements at the functional level. Moreover, it could be adopted as a more general methodology to identify candidate genes involved in other physiological processes, by tying their expected effects to deleterious outcomes through synthetic biology constructs and screening surviving mutants by sequencing.

**MATERIALS AND METHODS**

**Organisms and growth conditions**

Strains, media and growth conditions used in this study are listed in Table S1. If required, antibiotics, vitamin B_{12} (cyanocobalamin) and thiamine were added to the medium at concentrations indicated.

Algal culture density was measured using a Z2 particle count analyser (Beckman Coulter Ltd.) and optical density (OD) at 730 nm was measured using a FluoStar OPTIMA (BMG labtech) plate reader or a CLARIOstar plate reader (BMG labtech). Bacterial growth was recorded by measuring OD_{595}.

**Algal B_{12}-uptake assay**

Algal cultures were grown to stationary phase and cyanocobalamin salt (Sigma) was added (*Phaeodactylum tricornutum*: 600 pg; *Chlamydomonas reinhardtii*: 150 pg) to 5 x 10^6 cells in a final volume of 1 ml in f/2 or TAP medium respectively. The samples were incubated at 25°C under continuous light with shaking for 1 hour and inverted every 30 minutes to aid mixing. Samples were centrifuged and the supernatant (media fraction) transferred into a fresh microcentrifuge tube. The cell
pellet was resuspended in 1 ml water. Both samples were boiled for 10-20 minutes to release any cellular or bound B$_{12}$ into solution, and then centrifuged to pellet debris. The supernatant was used in the S. typhimurium B$_{12}$ bioassay as described in Bunbury et al. (2020). The amount of B$_{12}$ in the sample was calculated by comparison to a standard curve of known B$_{12}$ concentrations fitted to a 4 parameter logistic equation $f(x) = c + (d-c)(1+\exp(b\log(x)-\log(e)))$ (Ritz et al., 2015). This standard curve was regenerated with every bioassay experiment.

Generating P. tricornutum CBA1 knockout lines using CRISPR-Cas9

CRISPR/Cas9 genome editing applied the single guide RNA (sgRNA) design strategy described in Hopes et al., (2017). Details are provided in the Supplemental methods. P. tricornutum CCAP 1055/1 cells were co-transformed with linearised plasmids pMLP2117 and pMLP2127 (Supplemental Table 2) using a NEPA21 Type II electroporator (Nepa Gene) as previously described (Yu et al., 2021). After plating on 1% agar selection plates containing 75 mg·l$^{-1}$ zeocin and incubation for 2-3 weeks, zeocin resistant colonies were picked into 96 well plates containing 200 µl of f/2 media with 75 mg·l$^{-1}$ zeocin. After seven days strains were subcultured into fresh media either containing 75 mg·l$^{-1}$ zeocin or 300 mg·l$^{-1}$ nourseothricin, and genotyped with a three-primer PCR using PHIRE polymerase (Thermo Fisher Scientific) with primers gCBA1.fwd, gCBA1.rv and NAT.rv (Supplemental Table S3). Five promising colonies resistant to nourseothricin and with genotypes showing homologous recombination or indels were re-streaked on 75 mg·l$^{-1}$ zeocin f/2 plates to obtain secondary monoclonal colonies. Twelve secondary colonies were picked for each primary colony after 2-3 weeks and again genotyped with a three-primer PCR. Promising colonies were genotyped in further detail with primer pairs gCBA1.fwd/gCBA1.rv, gCBA1.fwd/NAT.rv and gCBA1in.fwd/gCBA1in.rv (Supplemental Table S3).

Construct assembly and C. reinhardtii transformation

Constructs were generated using Golden Gate cloning, using parts from the Chlamydomonas MoClo toolkit (Crozet et al., 2018) and some that were created in this work. All parts relating to Cre02.g081050 were domesticated from UVM4 genomic DNA, with BpiI and BsaI sites removed.
from the promoter, ORF and terminator by PCR-based mutagenesis using primers listed in Supplemental Table S3. A list of plasmids used in this study is shown in Supplemental Table S2.

Transformation of *C. reinhardtii* cultures with linearised DNA was carried out by electroporation essentially as described by Mehrshahi et al. (2020) before plating on TAP-agar plates with the appropriate antibiotics.

Insertional mutagenesis was performed as above, however, cultures were grown to a density of approximately 1x10⁷ cells/ml and were incubated with 500 ng transgene cassette. After allowing the cells to recover overnight in TAP plus 60 mM sucrose at 25°C in low light (less than 10 μmol photon m⁻².s⁻¹ at 100 rpm), between 200 - 250 μl of transformants were plated on solid TAP media (square 12x12 cm petri dishes) containing ranges of 15-20 μg/ml hygromycin, 20-50 μg/ml paromomycin and 48-1024 ng/l vitamin B12, and the plates were incubated in standing incubators.

**Confocal laser scanning microscopy**

*C. reinhardtii* transformants carrying the pAS_C2 construct were imaged in a confocal laser scanning microscope (TCS SP8, Leica Microsystems, Germany) with an HC PL APO CS2 40x/1.30 aperture oil-immersion lens. Images were taken using the sequential mode provided by the Leica LAS software, with the channel used for mVenus and brightfield detection being taken first and the channel used for chlorophyll detection taken second. The first image was acquired with excitation from a white light source at 486 nm at 7% power and emissions were detected between 520 - 567 nm; mVenus settings included 100% gain, gating between 0-8.24 ns and a reference line at 486 nm. Brightfield imaging used 610% gain and a 0% offset. Frames were captured with a line average of 4 and a frame accumulation of 2. The second image was acquired with excitation from a white light source at 514 nm at 2% power and emissions were detected between 687 - 724 nm with 50% gain. Frames were captured with a line average of 4 and a frame accumulation of 1. The overlay images were produced automatically by the Leica LAS software. Inkscape was used to increase the lightness and decrease the contrast of all the images in the same manner.
Reverse transcription quantitative PCR

Quantification of steady state levels of transcripts was carried out according to Bunbury et al. (2020), using random hexamer primers for cDNA synthesis. The RT-qPCR data was analysed using the ΔΔCT method with an assumed amplification efficiency of 2. Log2(2-ΔCT) values were plotted in the resulting figures.

Whole genome sequencing

Genomic DNA was extracted from C. reinhardtii cells by phenol-chloroform extraction and sequenced using the NovaSeq sequencing platform by Novogene (Cambridge, UK) to produce 150 bp paired-end reads. This involved RNase treatment and library preparation with the NEBNext Ultra II DNA Library Prep Kit (PCR-free), which generated 350 bp inserts. The raw sequencing data for this study have been deposited in the European Nucleotide Archive (ENA) at EMBL-EBI under accession number PRJEB58730 (https://www.ebi.ac.uk/ena/browser/view/PRJEB58730). Novogene performed all quality filtering, summary statistics and bioinformatic analysis. The location of the Hyg3 cassette was determined by identifying loci that comprised reads from IM4 that mapped between genomic DNA and pHyg3, and cross-referencing these loci against the parental strains. The TE identification was carried out similarly, full details are provided in Supplemental Methods.

Bioinformatics pipeline

The EukProt database was assessed for the presence of METE, METH and CBA1 (Richter et al., 2022). The query used for CBA1 was a hidden Markov model (HMM) generated from the protein fasta sequences: Phatr3_J48322, Thaps3_11697, Fracy1_241429, Fracy1_246327, Auran1_63075, Ectocarpus siliculosus D8LMT1 and Cre02.g081050.t1.2 by first aligning using MAFFT (Katoh and Standley, 2013) version 7.470 with the --auto option, and then building a HMM using hmmbuild (hmmer 3.2.1). Additionally, protein fasta (Cre06.g250902, Cre03.g180750), PFAM (PF02310, PF02965, PF00809, PF02574, PF01717, PF08267) and KO (K00548, K00549) queries were searched against EukProt to identify sequences with similarity to METE and METH. The queries were searched against EukProt using hmmsearch (HMMER 3.1b2). The default bitscore thresholds were
used for KO and PFAM queries. The threshold used for CBA1 HMM, and the CrMETE and CrMETH protein fasta sequences, was a full-length e-value of 1e-20. For each protein, all individual queries were required to be significant to classify the protein as present. The best hit in each species was identified by taking the protein with the greatest geometric mean of full length bitscores for the queries. The dataset was joined with taxonomic information from EukProt and completeness information calculated using BUSCO version 4.1.4 and eukaryote_odb10 (Manni et al., 2021).

**Accession Numbers**

Sequence data from this article can be found in the GenBank/EMBL data libraries under accession numbers_ PRJEB58730 ([https://www.ebi.ac.uk/ena/browser/view/PRJEB58730](https://www.ebi.ac.uk/ena/browser/view/PRJEB58730)).

**Supplemental Data**

Supplemental Figure S1. Characterization of B₁₂ uptake in *C. reinhardtii* insertional mutant lines.

Supplemental Figure S2. Visualization of B₁₂-BODIPY uptake in *C. reinhardtii* using confocal microscopy.

Supplemental Figure S3. *C. reinhardtii* knockout lines of *Cre12.g508644* are able to take up B₁₂.

Supplemental Figure S4. Structure and sequence of a second insertion in the IM4 strain.

Supplemental Figure S5. The predicted structures of CrCBA1 and PtCBA1 show a high degree of structural similarity.

Supplemental Figure S6. Independent mutant lines of *CrCBA1* show defective B₁₂ uptake.

Supplemental Figure S7. Sequences with similarity to CBA1 are found throughout Eukaryota.

Supplemental Table S1. Table of strains used in this work.

Supplemental Table S2. Plasmids used in this study.

Supplemental Table S3. Oligonucleotides used in this study.
Supplemental Table S4. Protein sequences with similarity to CBA1 used for tree building in Figure 613 S7.

Supplemental Table S5. Summary of CBA1, METE and METH presence/absence found in organisms within Supergroups with greater than 5 organisms with a completeness greater than 70% and at least one of: METE or METH.

Acknowledgements

We thank Catherine Sutherland for help with maintaining and screening the CRISPR/Cas9 mutants of *P. tricornutum* and Dr Lorraine Archer for lab management. We are grateful to Dr Amanda Hopes and Prof Thomas Mock (University of East Anglia) for the parts used in gene editing of *PtCBA1*. The plasmid Hyg3 used in the insertional mutagenesis was obtained from the Chlamydomonas Resource Centre (www.chlamycollection.org). For the purpose of open access, the authors have applied a Creative Commons Attribution (CC BY) licence to any Author Accepted Manuscript version arising from this submission.
Author contributions

APS designed and performed research, analysed data and wrote the article with contributions from all the authors. KG and MLP carried out the CRISPR/Cas9 editing of *P. tricornutum* and contributed to writing the article. AH carried out the bioinformatics analysis to identify the putative transposable elements. FB performed the metE7 RT-qPCR and B₁₂ uptake assays. MJW & ADL synthesised the BODIPY-labelled B₁₂ and contributed to writing the article. KG, GMO and PM supervised aspects of the project and contributed to writing the article. AGS conceived the project, obtained the funding, supervised the project and wrote the article with contributions from all the authors. AGS agrees to serve as the author responsible for contact and ensures communication.

Figure Legends

**Figure 1. Disruption of Phaeodactylum tricornutum CBA1 (PtCBA1) using CRISPR-Cas9 yielded lines with impaired B₁₂ uptake.** a) Schematic showing CRISPR-Cas9 sgRNA target sites and the homology repair template design used to generate mutant lines in *PtCBA1* (Phatr3_J48322). The homology repair template schematic is annotated with the 5’ homology region (HR) and 3’HR, the FCPB promoter, nourseothricin resistance gene (*NAT*) and FCPC terminator. The *PtCBA1* gene is annotated with the ORF, the 5’HR and 3’HR regions used in the homology template and the regions of the ORF targeted by sgRNA (vertical bars). Primer positions used for the analysis of putative mutant lines are shown with arrowheads. b) PCR of regions across and within wild-type (WT) and mutant *PtCBA1* in 3 independent CRISPR-Cas9 lines (∆CBA1) showing indel mutations in the mutants. PCR products from different sets of primers indicated in panel a are shown. M = marker, - Ctrl = no DNA template. c) A B₁₂ uptake assay was performed as described in Materials and Methods, to determine the amount of B₁₂ in the media and the cells after 1h incubation of *P. tricornutum* cells in 600 pg B₁₂. The ‘Total’ was inferred by the addition of the cell and media fractions. The dashed line indicates the amount of B₁₂ added to the experiment. Standard deviation error bars are shown, n=4. Statistical analysis was performed on the media fraction, and Tukey’s test identified the following comparisons to be significantly different from one another: WT vs No Algae (p<1e⁻¹²); WT vs ∆CBA1-1 (p<1e⁻¹⁰); WT vs ∆CBA1-2 (p<1e⁻¹²); WT vs ∆CBA1-3 (p<1e⁻¹¹); No Algae vs ∆CBA1-1 (p<1e⁻⁰³); No Algae vs ∆CBA1-3 (p<0.05); and ∆CBA1-1 vs ∆CBA1-2 (p<1e⁻⁰²).

**Figure 2. Generation and use of C. reinhardtii reporter strain UVM4-T12 for insertional mutagenesis.** a) Schematic of the constructs used for insertional mutagenesis of *C. reinhardtii*. The pAS_R1 construct was designed to control expression of the paromomycin resistance gene (*aphVIII*) via B₁₂ mediated repression of the *METE* promoter (*P*₇₈). The pHyg3 construct encoded a constitutively expressed hygromycin resistance gene (*aphVII*), to be used for insertional mutagenesis. b) Growth of *C. reinhardtii* B₁₂ reporter strain UVM4-
25 T12 bearing pAS_R1 plasmid, in response to vitamin B12 and paromomycin concentration in
the media according to the algal dose-response assay. The predicted dose-response model is
shown in black, with 95% confidence intervals in grey.

**Figure 3.** *C. reinhardtii* insertional mutant 4 (IM4) is defective in B12 response and
uptake, and can be functionally complemented with CrCBA1. a) Effect of vitamin B12 on
METE gene expression in UVM4 and IM4, determined by RT-qPCR. UVM4 and IM4 were
grown in TAP media with or without 1000 ng·l⁻¹ vitamin B12 for 4 days at 25°C, 120 rpm and
in continuous light (90 µE·m⁻²·s⁻¹). Boxplots of the log₂ transformed expression level of
METE relative to that in the control (no B₁₂) sample are shown, n=6. The boxplots show the
median (center line), 25th and 75th percentile hinges, and whiskers extending to the value no
further than 1.5 times the interquartile range; values beyond this are plotted
individually. Significant comparisons were identified using Tukey’s test: UVM4 + 1000 ng·l⁻¹
vitamin B12 from UVM4 No Addition (p<1e⁻⁰⁸), IM4 No Addition (p<1e⁻⁰⁸) and IM4 +
1000 ng·l⁻¹ vitamin B12 (p<1e⁻⁰⁷). b) Schematic of the Cre02.g081050 gene showing the
position of the insertion site (indicated with a black triangle) determined by whole genome
sequencing (Figure S4). c) Schematic of the pAS_C2 construct designed to express CrCBA1
fused to the fluorescent reporter mVenus. CrCBA1-mVenus was under the control of the
CrCBA1 promoter and terminator. pAS_C2 also contained the spectinomycin resistance gene
aadA, driven by the PSAD promoter and PSAD terminator. d) B₁₂-uptake assay with UVM4,
IM4 and IM4::pAS_C2 (n = 4 separate transformants with high mVenus expression). Dashed
line indicates the amount of B₁₂ added to the assay. Standard deviation error bars are shown.
Statistical analysis was performed on the media fraction, and Tukey’s test identified the
following comparisons to be significantly different from one another: No Algae vs UVM4
(p<1e⁻⁰⁸); No Algae vs IM4 (p<0.05); No Algae vs IM4::pAS_C2 (p<1e⁻⁰⁸); UVM4 vs 1.G2
(p<1e⁻⁰⁹); and 1.G2 vs 1.G2::pAS_C2 (p<1e⁻⁰⁸).

**Figure 4.** CLiP mutants in CrCBA1 are impaired in their ability to take up B₁₂. a)
Schematic of the pAS_C3 construct designed to express CrCBA1 in a controllable manner
using a thiamine repressible riboswitch (RS,Thi4.4N) to allow repression of CrCBA1 through
the addition of thiamine (Mehrshahi et al., 2020). b) B₁₂-uptake assay with cw15, LMJ-
040682 (mean of 4 independent transformants) and LMJ-040682::pAS_C2 and LMJ-
040682::pAS_C3 (mean of 3 independent transformants). The growth conditions were
modified compared to previous assays: lines were grown with or without 10 µM thiamine
supplementation for 5 days in a 16/8 light/dark cycle, and 8 hours after the dark to light
transition the cultures were used for the algal B₁₂-uptake assay. The dashed line indicates the
amount of B₁₂ added to the sample. Standard deviation error bars are shown. Statistical
analysis was performed on the media fraction. Tukey’s test identified the following algal
strains to be significantly different from one another in media without thiamine (not reporting
comparisons against the No Algae control condition): cw15 vs LMJ-040682 (p<1e⁻¹⁰); LMJ-
040682 vs LMJ-040682::pAS_C2 (p<1e⁻⁰⁹); and LMJ-040682 vs LMJ-040682::pAS_C3
(p<1e⁻⁰⁹). Additionally, Tukey’s test found the following strain to show a significant
difference due to thiamine addition: LMJ-040682::pAS_C3 (p<1e⁻⁰⁷).

**Figure 5.** Confocal microscopy of complemented *C. reinhardtii* CrCBA1 knockout lines
showing an association between CrCBA1 and membranes. LMJ-040682 and LMJ-
040682::pAS_C2 A10 and D10 lines were imaged according to the protocol outlined in the
materials and methods. Channels shown (left to right) are brightfield, chlorophyll, mVenus and an overlay. Microscope settings are described in Methods.

**Figure 6. CBA1 expression and B12 uptake capacity in a B12-dependent mutant of C. reinhardtii (metE7) during B12 starvation and add-back.** a) Log2 transformed expression level of CBA1 measured by RT-qPCR and presented relative to levels in control conditions (B12 replete). Vertical dashed lines denote when B12 was removed and added. b) B12 uptake capacity of starved metE7 cells (expressed as 10⁶ molecules of B12 per cell over 1h) at the same 6 time points during B12 starvation; it was not possible to perform the uptake assay on cells to which B12 had already been added. Cell density measurements were performed by counting plated cells in dilution series, and so included non-viable cells. For CBA1 expression and B12 uptake, 3 and 6 biological replicates were used, respectively, with points representing means, and error bars representing standard deviations.

**Figure 7. Distribution of CBA1 and methionine synthase sequences across Eukaryotic groups.** The EukProt database (Richter et al., 2022) was searched for METE, METH and CBA1 queries, as described in the materials and methods. Organisms were only considered if they contained at least one valid methionine synthase hit (METE or METH) and their genomes were >70% complete, as measured by BUSCO (Manni et al., 2021). Eukaryotic classes were filtered for those with greater than 5 genomes and the numbers of taxa for each class are indicated in brackets. The different combinations of CBA1, METE and METH were calculated for each species (Supplemental Table S4) and summarised as a percentage of the total number of taxa in each class, with gradual shading to show the variation in distribution between the different classes.

**Figure 8. Identification and predicted structural location of CrCBA1 conserved residues.** a) Sequences with similarity to CBA1 were identified from the EukProt database (Richter et al., 2022) using a manually generated CBA1 Hidden Markov Model (HMM), as described in the materials and methods. A selection of 16 taxa from several eukaryotic supergroups were chosen and conserved regions from the protein are presented. Specific residues indicated by * are: K78, P118, L136, E206, F214, F215, N216, E218, P251, V253, W255, G289, W394, F395, E396 and D408. Protein sequences are coloured according to the Clustal colour-scheme using Geneious Prime 2021.1.1 (www.geneious.com). For each highly conserved region, the corresponding position and amino acid from the CrCBA1 sequence (Cre02.g081050) is indicated. b) The predicted 3D structure of CrCBA1 (residues 21-490) was obtained from the AlphaFold Protein Structure Database (entry: A0A2K3E0J7). Highly conserved regions of CrCBA1 are indicated in light blue and labelled. CrCBA1 was aligned to the crystal structure of E. coli BtuF in complex with B12 (pdb: 1n2z). This enabled the relative position of B12 (shown in red) to be superimposed onto CrCBA1.

Figure 1. Disruption of *Phaeodactylum tricornutum CBA1 (PtCBA1)* using CRISPR-Cas9 yielded lines with impaired B$_{12}$ uptake. 

**a)** Schematic showing CRISPR-Cas9 sgRNA target sites and the homology repair template design used to generate mutant lines in *PtCBA1* (Phatr3_J48322). The homology repair template schematic is annotated with the 5’ homology region (HR) and 3’HR, the *FCPB* promoter, nourseothricin resistance gene (*NAT*) and *FCPC* terminator. The *PtCBA1* gene is annotated with the ORF, the 5’HR and 3’HR regions used in the homology template and the regions of the ORF targeted by sgRNA (vertical bars). Primer positions used for the analysis of putative mutant lines are shown with arrowheads. 

**b)** PCR of regions across and within wild-type (WT) and mutant *PtCBA1* in 3 independent CRISPR-Cas9 lines (∆CBA1) showing indel mutations in the mutants. PCR products from different sets of primers indicated in panel a are shown. M = marker, - Ctrl = no DNA template. 

**c)** A B$_{12}$ uptake assay was performed as described in Materials and Methods, to determine the amount of B$_{12}$ in the media and the cells after 1h incubation of *P. tricornutum* cells in 600 pg B$_{12}$. The ‘Total’ was inferred by the addition of the cell and media fractions. The dashed line indicates the amount of B$_{12}$ added to the experiment. Standard deviation error bars are shown, n=4. Statistical analysis was performed on the media fraction, and Tukey’s test identified the following comparisons to be significantly different from one another: WT vs No Algae (p<1e$^{-12}$); WT vs ∆CBA1-1 (p<1e$^{-13}$); WT vs ∆CBA1-2 (p<1e$^{-12}$); WT vs ∆CBA1-3 (p<1e$^{-11}$); No Algae vs ∆CBA1-1 (p<1e$^{-03}$); No Algae vs ∆CBA1-3 (p<0.05); and ∆CBA1-1 vs ∆CBA1-2 (p<1e$^{-02}$).
Figure 2. Generation and use of *C. reinhardtii* reporter strain UVM4-T12 for insertional mutagenesis. 

**a)** Schematic of the constructs used for insertional mutagenesis of *C. reinhardtii*. The pAS_R1 construct was designed to control expression of the paromomycin resistance gene (*aphVIII*) via B12 mediated repression of the METE promoter (*P_{METE}*). The pHyg3 construct encoded a constitutively expressed hygromycin resistance gene (*aphVII*), to be used for insertional mutagenesis.

**b)** Growth of *C. reinhardtii* B12 reporter strain UVM4-T12 bearing pAS_R1 plasmid, in response to vitamin B12 and paromomycin concentration in the media according to the algal dose-response assay. The predicted dose-response model is shown in black, with 95% confidence intervals in grey.
a) Relative level of METE expression (log2) with Vitamin B₁₂ (ng/l) added to media.

b) Gene Cre02.g081050 insertion site of putative mobile genetic element.

c) Cre02.g081050 cassette with Promoter, ORF, mVenus, Terminator.

d) pg of B₁₂ in fraction with No Algae, UVM4, IM4, IM4::pAS_C2.
Figure 4. 

CLiP mutants in CrCBA1 are impaired in their ability to take up B12. 

a) Schematic of the pAS_C3 construct designed to express CrCBA1 in a controllable manner using a thiamine repressible riboswitch (RS_THIA_4N) to allow repression of CrCBA1 through the addition of thiamine (Mehrshahi et al., 2020).

b) B12-uptake assay with cw15, LMJ-040682 and mean of 3 independent transformants of LMJ-040682::pAS_C2 and LMJ-040682::pAS_C3. The growth conditions were modified compared to previous assays: lines were grown with or without 10 µM thiamine supplementation for 5 days in a 16/8 light/dark cycle, and 8 hours after the dark to light transition the cultures were used for the algal B12-uptake assay. The dashed line indicates the amount of B12 added to the sample. Standard deviation error bars are shown. Statistical analysis was performed on the media fraction. Tukey’s test identified the following algal strains to be significantly different from one another in media without thiamine (not reporting comparisons against the No Algae control condition): cw15 vs LMJ-040682 (p<1e-10); LMJ-040682 vs LMJ-040682::pAS_C2 (p<1e-09); and LMJ-040682 vs LMJ-040682::pAS_C3 (p<1e-09). Additionally, Tukey’s test found the following strain to show a significant difference due to thiamine addition: LMJ-040682::pAS_C3 (p<1e-07).
