21

22 **Abstract**

23 Data Deficient species (DD) comprise a significant portion of the total number of
24 species listed within the IUCN Red List. Although they are not classified within one of
25 the threat categories, they may still face high extinction risks. However, due to limited
26 data available to infer their extinction risk reliably, it is unlikely that the assessment of
27 the true status of Data Deficient species would be possible before many species decline
28 to extinction. An appropriate measure to resolve these problems would be to introduce
29 a flag of Potentially Threatened species within the Data Deficient category (i.e.,
30 DD(PT)). Such a flag would represent a temporary Red List status for listed Data
31 Deficient species that are, based on the available direct evidence and/or indirect indices,
32 likely to be assigned to one of the threat categories, but where current data remains
33 insufficient for a complete classification. The use of such a flag could increase the
34 focus of the scientific community and conservation decision-makers on such species,
35 thus avoiding the risk that necessary conservation measures are implemented too late.
36 As such, establishment of the DD(PT) category as a kind of alarm for priority species
37 could be beneficial.

38

39 **Keywords:** Data Deficient; endangered species; extinction risk; IUCN Red List;
40 threatened species.

41

42 The IUCN Red List of Threatened Species is considered as one of the most
43 relevant information sources and decision-making support tools for conservation
44 management (Rodrigues et al. 2006; IUCN 2015). However, for many species, limited
45 or insufficient data are available on their geographic distribution, abundance,
46 population trends and threats to infer their extinction risk reliably. This leaves those
47 conducting assessments in a dilemma: based on available data and acknowledging the
48 associated uncertainties, can a classification other than Data Deficient (DD; IUCN
49 2001) be made? How assessors incorporate and handle the uncertainties associated with
50 poorly known species can result in the difference between a species being listed as Data
51 Deficient or as threatened.

52 Data Deficient species represent as much as 16% of the total number of species
53 listed within the IUCN Red List (i.e., approximately 13,000 out of the 80,000 species
54 assessed so far are classified as Data Deficient; IUCN 2015). Although they are not
55 classified within the threat categories, Data Deficient species may still face high
56 extinction risks, and may actually be more frequently threatened than successfully
57 evaluated species (Howard and Bickford 2014; Bland et al. 2015; Jetz and Freckelton
58 2015; Roberts et al. 2016). This problem was also illustrated by recent population
59 declines reported in some Data Deficient species (Morais et al. 2013). Many of these
60 species may in fact be perilously close to extinction (Schipper et al. 2008).

61 At the same time, such species may be neglected by research and
62 conservation programs, with funding rarely being directed to address specifically the
63 problem of Data Deficient species (Morais et al. 2013; Bland et al. 2015). Lack of
64 conservation focus is mainly driven by their uncertain conservation status (Bland et al.
65 2015), as well as by the tendency of conservation managers to prioritize well-studied

66 species (Sitas et al. 2009). The Data Deficient category is essentially different from the
67 other categories, since its listing does not imply that a taxon is not threatened, but
68 represents an expression of necessity for additional efforts by researchers.

69 Assessment of the true status of Data Deficient species could be achieved
70 through focused field surveys (Bland et al. 2015). However, given the necessary time,
71 man-power and monetary implications in collecting baseline data on all Data Deficient
72 species, it is unlikely that this would be possible before populations of many species
73 decline, potentially to extinction (Howard and Bickford 2014; Bland et al. 2015). Given
74 the very large number of species classified as Data Deficient, there is also a need to
75 prioritize those that should be studied first and removed from this category, with
76 prioritization primarily on the grounds of potential threat.

77 We suggest that one of the appropriate measures to resolve this problem
78 would be to introduce a flag of Potentially Threatened species within the Data Deficient
79 category (i.e., DD(PT)), as a temporary Red List status that would warn that such
80 species are potentially threatened and that monitoring, research and conservation
81 attention are required. The idea behind such a flag follows the establishment of the flag
82 of potentially extinct species within the Critically Endangered category (CR(PE);
83 Butchart et al. 2006), as both flags represent temporary classifications until more
84 detailed information are made available to confirm suspected species status.

85 We define Potentially Threatened Data Deficient species as those that are,
86 based on available direct evidence and/or indirect indices, likely to be assigned to one
87 of the threat categories (i.e., VU, EN or CR), but where current data remains
88 insufficient for a complete classification. It is important to emphasize that the liberal
89 use of the Data Deficient category should be discouraged, and all species with

90 sufficient information for their inclusion within one of the threat categories should be
91 classified as such (IUCN 2001). Furthermore, we advise against the direct use of
92 DD(PT) flag for newly assessed species, to avoid further inflation of the Data Deficient
93 category; it should be preferably applied only to the current Data Deficient species, i.e.
94 those that have been classified as such within previous assessments.

95 Although Data Deficient species lack information needed for a Red List
96 classification, large amounts of life-history, ecological, and phylogenetic information
97 may be available for many of these species (Bland et al. 2015). While these data alone
98 can be technically insufficient for making a standardized decision on classifying a
99 species into one of the ‘data-sufficient’ categories, they can be nevertheless used for
100 indirect threat assessments. In recent years, a number of indirect assessment methods
101 have been applied to Data Deficient species within different groups, mainly mammals
102 and amphibians, to infer their likely threat level (Table 1). Most frequently used
103 approaches were machine-learning methods, largely based on information related to
104 geographic range, life-history and ecological data, phylogeny, environmental data and
105 threat intensity (Howard and Bickford 2014; Bland et al. 2015). The general
106 characteristic of all the methods was their attempt to model the relationship between
107 different types of information related to ‘data-sufficient’ species and their Red List
108 classification, and to apply it thereafter to Data Deficient species based on the available
109 information. Such methods should be considered as sufficient evidence for classifying
110 assessed species within the DD(PT) category. The proportion of Data Deficient species
111 considered to be potentially threatened varied between studies; for instance, predictions
112 for Data Deficient mammal species ranged from 35% (Jones and Safi 2011) to 69%
113 (Jetz and Freckelton 2015; Table 1). However, in accordance with the precautionary

114 principle, each species identified as potentially threatened with extinction by one or
115 several of the applied methods should be a candidate for the DD(PT) category. From a
116 conservation perspective, it would be more problematic to incorrectly deny the DD(PT)
117 status to a species than to incorrectly attribute it. Conversely, species identified by all
118 the methods as likely to be not-threatened would remain within the general Data
119 Deficient category until sufficient data and analyses can identify their adequate threat
120 category.

121 Beside the methods listed in Table 1, other methods designed for extinction
122 risk assessment of data-poor species could also be applied, based on the type and the
123 amount of available data. For instance, for many Data Deficient species, biological
124 collections or sighting records represent the only available data (Roberts et al. 2016). In
125 such situations, application of methods that infer threat based on the observation
126 records would be appropriate (e.g. Burgman et al. 1995, 2000; McCarthy 1998; Regan
127 et al. 2000; McInerny et al. 2006; Robbirt et al. 2006).

128 However, the recognition of DD(PT) flag for species already in the Data
129 Deficient category would contribute to the better research and conservation
130 prioritization of those species for which a sound classification other than Data Deficient
131 cannot be made. The use of such a flag would reduce the risk of these species being
132 neglected by the scientific community and conservation decision-makers, to the point
133 when postponed conservation measures are implemented too late. Establishment of the
134 DD(PT) flag could be highly beneficial as a temporary measure, designed to highlight
135 the status of such species. Given that they are also likely to be threatened with
136 extinction, species classified as DD(PT) should be recognised as a major research
137 priority. Research efforts are expected to be more effective and yield more critical

138 knowledge if they are directed to the least known species (de Lima et al. 2011). Given
139 that they are also likely to be threatened with extinction, species classified as DD(PT)
140 should be recognised as a major research priority.

141 Classification of DD(PT) species could also serve as a platform to instigate
142 and enhance communication within the scientific community on the true status of such
143 species. One of the primary roles of the IUCN Red List is to contribute to conservation
144 efforts, as a communication tool for decision-makers, funding sources, scientific
145 community and the general public. Establishment of the DD(PT) category as a kind of
146 alarm for potential priority species would fit this purpose and likely prove to be a
147 highly beneficial tool, with the scientific community and managers involved in
148 monitoring programs as its major end-users.

Table 1. Examples of studies that involved indirect estimation of extinction threat for Data Deficient species.

Reference	Assessed DD species	Method	Used data	Results
Davidson et al. 2009	Mammals	Decision-tree modelling, classification tree and random forest modelling	11 explanatory variables; geographic range, density, group size, mass-specific production, home range, body mass, habitat mode and activity period identified as relevant predictors	28 out of 341 assessed species (8%) determined to be at high extinction risk
Jones and Safi 2011	Mammals	Combination of spatial eigenvector estimation and phylogenetic eigenvectors	Phylogenetic, distribution and environmental data	35% of 481 assessed species determined to be threatened with extinction
Morais et al. 2013	Brazilian anuran species	Quantile regression to model a relationship between the time since species discovery and range-size	Time since species description and current species distribution	37 of 231 assessed species (16%) determined to be threatened with extinction, overall rate likely 57%
Howard and Bickford 2014	Amphibians	Machine-learning method, random forest models	Extinction risk data and distribution ranges	63% of 1249 assessed species determined to be probably threatened with extinction
Quintero et al. 2014	Mexican amphibians	Machine-learning method, random forest models	14-15 explanatory variables, including data on species' life history and population trends, environmental data and negative impacts	18 out of 24 assessed species (75%) determined to be declining
Bland et al. 2015	Terrestrial mammals	Seven machine learning methods: classification tree, random forest, boosted tree, k nearest neighbours,	29-36 explanatory variables, including data on species' life history and ecology, environmental data and	313 of 493 assessed species (63%) determined to be threatened with extinction

		support vector machine, neural network, and decision stumps	measures of threat intensity	
Jetz and Freckelton 2015	Mammals	Spatial-phylogenetic statistical framework, generalized linear models, generalized least-squares approach	Body mass, distribution and encroachment (anthropogenic habitat transformation) data	331 of 483 assessed species (69%) determined to be threatened with extinction
Luiz et al. 2016	Groupers (Teleostei: Epinephelidae)	Ordinal analytical approach, cumulative link mixed-effects modelling	Body-size, maximum depth of occurrence, breadth of habitat use, geographic range size, aggregative spawning behaviour, and biogeographical region	6 of 50 assessed species (12%) determined to be endangered or vulnerable
