Stringy invariants for horospherical varieties of complexity one

Kevin Langlois, Clélia Pech and Michel Raibaut

ABSTRACT

We determine the stringy motivic volume of log terminal horospherical varieties of complexity one and obtain a smoothness criterion using a comparison of stringy and usual Euler characteristics.

1. Introduction

Motivic integration is a natural geometric counterpart to p -adic integration. It is a powerful tool for creating new invariants for algebraic varieties such as stringy invariants; see [Bat98]. In [BM13], stringy invariants were instrumental in simplifying a smoothness criterion for embeddings of horospherical homogeneous spaces; however, for general spherical varieties, the formulation of this criterion remains a conjecture; see [BM13, Conjecture 6.7].

In this paper, we study stringy invariants of \mathbb{Q} -Gorenstein horospherical varieties of complexity one with log terminal singularities. One of our results, Theorem 5.16, provides an explicit formula for stringy invariants in terms of their combinatorial description. We also obtain a rational form for the stringy motivic volume and, using convex geometry, an explicit finite set of candidate poles; see Theorem 5.23. Finally, under additional assumptions, we rephrase in Theorem 6.4 a smoothness criterion for these varieties in terms of the stringy Euler characteristic.

Throughout, we work over the complex numbers. We denote by G a connected, simply connected, reductive, linear algebraic group and by B a Borel subgroup. By “simply connected” we mean that $G = G^{\text{ss}} \times F$, where G^{ss} is a simply connected semisimple group in the usual sense and F is an algebraic torus. A G -homogeneous space G/H , where H is a closed subgroup, is *horospherical* if H contains a maximal unipotent subgroup of G . These spaces are locally trivial torus fiber bundles $G/H \rightarrow G/P$ over flag varieties, where P is the parabolic subgroup normalizing H . The fibers are isomorphic to the algebraic torus $T = P/H$. The character lattice of T and the set of simple roots indexing the Schubert divisors in G/P entirely describe G/H ; see Section 3.1.

A *horospherical G -variety* is a normal G -variety such that every orbit is horospherical. Its *complexity* is the minimum of the codimensions of its G -orbits. Horospherical varieties of complexity at most one admit a combinatorial description in terms of objects coming from convex

geometry, almost analogous to the classical situation for toric varieties. This combinatorial description was introduced by Timashev in [Tim97] and adapted from Luna–Vust theory [Tim11, Chapter 3]; see also [LT16]. It goes as follows.

Consider a *simple G -variety* X , that is, a G -variety which contains an open affine B -stable subset which intersects every G -orbit of X . Any simple horospherical G -variety X of complexity one is described by a 4-tuple $(C, G/H, \mathfrak{D}, \mathcal{F})$, where C is a smooth projective curve and G/H is a horospherical G -homogeneous space. The pair $(C, G/H)$ encodes the birational equivariant type of X . The third datum \mathfrak{D} is a *polyhedral divisor* on C , that is, a Weil divisor on C whose coefficients are polyhedra; see Definition 3.1. Finally, \mathcal{F} denotes the set of B -stable prime divisors on X which are not G -stable and which contain a G -orbit of X . We call the pair $(\mathfrak{D}, \mathcal{F})$ a *colored polyhedral divisor*.

It follows from [Sum74] that any normal G -variety possesses a finite open covering by stable subsets which are simple G -varieties. Thus any horospherical G -variety of complexity one can be described by a triple $(C, G/H, \mathcal{E})$, where \mathcal{E} is a *colored divisorial fan* consisting of a certain finite collection of colored polyhedral divisors; see Definition 3.1.

The goal of this paper is to compute the stringy motivic volume of X in terms of $(C, G/H, \mathcal{E})$, under the assumption that X is a normal \mathbb{Q} -Gorenstein variety with log terminal singularities. For such X , let $f: X' \rightarrow X$ be a log resolution of singularities. The *stringy motivic volume* of X is the integral

$$\mathcal{E}_{\text{st}}(X) = \int_{\mathcal{L}(X')} \mathbb{L}^{-\text{ord } K_{X'/X}} d\mu_{X'}. \tag{1.1}$$

Here \mathbb{L} is the class of the affine line, $K_{X'/X}$ the relative canonical divisor, $\mathcal{L}(X')$ the *arc space* of X' , and the measure $\mu_{X'}$ takes values in a modification of the Grothendieck ring $K_0(\mathbf{Var}_{\mathbb{C}})$ of complex algebraic varieties.

The measure $\mu_{X'}$ can be explicitly described on particular subsets of $\mathcal{L}(X')$. Denote by π_n the truncation morphism sending an arc of X' to its n -jet. A subset $Z \subset \mathcal{L}(X')$ is a *cylinder* if there is an $n_0 \in \mathbb{N}$ such that for any $n \geq n_0$, the subset $\pi_n(Z)$ is a constructible set in the space of n -jets of X' and $Z = \pi_n^{-1}(\pi_n(Z))$. On the cylinders, the motivic volume is defined as

$$\mu_{X'}(Z) = [\pi_n(Z)] \mathbb{L}^{-n \dim X'}$$

and does not depend on the choice of $n \geq n_0$. Measurable subsets of $\mathcal{L}(X')$ are approximations of cylinders. The integral of a measurable function $F: \mathcal{L}(X') \rightarrow \mathbb{Z}$ with respect to $\mu_{X'}$ is the sum (if it exists) of the series $\sum_{s \in \mathbb{Z}} \mu_{X'}(F^{-1}(s)) \mathbb{L}^{-s}$.

Note that the stringy motivic volume has a rational form (see the alternative expression in Definition 2.5), and it is independent of the choice of a resolution of singularities; see [Bat98].

If X is toric with lattice N and fan Σ , let $\theta_X: |\Sigma| \rightarrow \mathbb{Q}$ be the piecewise linear function which takes value -1 on each primitive generator of the one-dimensional cones of Σ . Here $|\Sigma|$ denotes the union of all cones of Σ . Then

$$\mathcal{E}_{\text{st}}(X) = (\mathbb{L} - 1)^r \sum_{\nu \in |\Sigma| \cap N} \mathbb{L}^{\theta_X(\nu)}. \tag{1.2}$$

Equation (1.2) was proved in [BM13, Theorem 4.3], albeit in a more general setting. We follow the proof of loc. cit., which consists of two main steps.

Let K be a field extension of \mathbb{C} . The set $\mathcal{L}(X)(K)$ of K -points in the arc space $\mathcal{L}(X)$ of the toric variety X identifies with $X(\mathcal{O})$, where $\mathcal{O} = \mathcal{O}_K := K[[t]]$. The torus $T(\mathcal{O})$ naturally acts on $X(\mathcal{O}) \cap T(\mathcal{K})$, where \mathcal{K} is the fraction field of \mathcal{O} , and $X(\mathcal{O})$ and $T(\mathcal{K})$ are viewed as subsets

of $X(\mathcal{K})$. The set of orbits of $X(\mathcal{O}) \cap T(\mathcal{K})$ is in bijection with $|\Sigma| \cap N$; see [Ish04]. This yields natural cylinders $\mathcal{C}_\nu \subset \mathcal{L}(X)$ for any $\nu \in |\Sigma| \cap N$.

In the second step, we study the integral $\int \mathbb{L}^{-\text{ord } K_{X'/X}} d\mu_{X'}$ along each cylinder \mathcal{C}_ν , where $X' \rightarrow X$ is a desingularization given by a fan subdivision. Since $X'(\mathcal{O}) \cap T(\mathcal{K})$ identifies with $X(\mathcal{O}) \cap T(\mathcal{K})$ and the complement in $\mathcal{L}(X')$ has motivic measure zero, we obtain an equality

$$\int_{\mathcal{L}(X')} \mathbb{L}^{-\text{ord } K_{X'/X}} d\mu_{X'} = \sum_{\nu \in |\Sigma| \cap N} \int_{\mathcal{C}_\nu} \mathbb{L}^{-\text{ord } K_{X'/X}} d\mu_{X'}. \quad (1.3)$$

Equation (1.2) is then obtained by computing each summand of the right-hand side.

When adapting these two steps to horospherical varieties of complexity one, we encounter significant differences. For simplicity, let us explain these differences in the complexity one *toric* case; that is, assume that X is a normal \mathbb{Q} -Gorenstein T -variety of complexity one with log terminal singularities. We denote by (C, T, \mathcal{E}) the combinatorial data associated with X . The first step is then modified as follows. The variety X contains an open subset of the form $\Gamma \times T$, where $\Gamma \subseteq C$ is an open dense subset. Thus, comparing with the toric setting, it is natural to consider the action of $T(\mathcal{O})$ on

$$X(\mathcal{O}) \cap (\Gamma \times T)(\mathcal{K}). \quad (1.4)$$

However, when we follow the almost similar approach of Ishii [Ish04], we find uncountably many $T(\mathcal{O})$ -orbits. To solve this problem, we cut the set (1.4) in two disjoint pieces, namely the subset of *horizontal arcs* and the subset of *vertical arcs*. Thus, we obtain a partition of the set (1.4) by parts $\mathcal{C}_{(y,\nu,\ell)}$ which are $T(\mathcal{O})$ -stable and indexed by a countable set $|\mathcal{E}|_\Gamma \cap \mathcal{N}$ combinatorially determined by \mathcal{E} .

The second step consists in checking that each $\mathcal{C}_{(y,\nu,\ell)}$ is measurable, see Lemmas 4.14 and 4.15, and computing

$$\int_{\mathcal{L}(X')} \mathbb{L}^{-\text{ord } K_{X'/X}} d\mu_{X'} = \sum_{(y,\nu,\ell) \in |\mathcal{E}|_\Gamma \cap \mathcal{N}} \int_{\mathcal{C}_{(y,\nu,\ell)}} \mathbb{L}^{-\text{ord } K_{X'/X}} d\mu_{X'}, \quad (1.5)$$

where X' is obtained by an explicit desingularization determined by \mathcal{E} ; see Section 5.3.

The function $\theta_X: |\Sigma| \rightarrow \mathbb{Q}$ introduced above in the toric setting is a support function of a torus-invariant canonical divisor. This analogy between support functions and Cartier \mathbb{Q} -divisors persists for horospherical varieties of complexity one; see Section 5.2. However, it is not possible, adapting the proofs in [BM13], to directly obtain a version involving the support function of an invariant canonical divisor. Instead we need to introduce an *auxiliary function* ω_X ; see Proposition-Definition 5.10. This ω_X does not define, in the usual sense, a Cartier \mathbb{Q} -divisor (see Section 6.1 for further details). Note that in [Lan17] we use ω_X for characterizing singularities related to the minimal model program.

Our main result can be stated as follows.

THEOREM 1.1. *Let X be a \mathbb{Q} -Gorenstein horospherical variety of complexity one with log terminal singularities and combinatorial data $(C, G/H, \mathcal{E})$. Assume that $\Gamma \subset C$ is a dense open subset which does not contain any special point (see Definition 3.11). Then*

$$\mathcal{E}_{\text{st}}(X) = [G/H] \left[\sum_{(y,\nu,\ell) \in |\mathcal{E}|_\Gamma \cap \mathcal{N}} [X_\ell] \mathbb{L}^{\omega_X(y,\nu,\ell)} \right],$$

where $X_0 = \Gamma$ and $X_\ell = \mathbb{A}^1 \setminus \{0\}$ if $\ell \geq 1$.

Let us give a brief summary of the contents of each section. In Sections 2 and 3, we introduce notation from motivic integration and horospherical varieties that we use throughout this paper. In Section 4, we study the arc space of a horospherical variety of complexity one. To do this, we proceed in two steps. First, we give a description in the case where the acting group is an algebraic torus; this corresponds to Sections 4.1 and 4.2. The last step concerns the general case, where we reduce to the case of torus actions by parabolic induction. We believe that the study in the first step might be interesting, independently, for the study of singularities of T -varieties.

In Section 5, we prove Theorem 1.1. One of the main ingredients of the proof is the construction by combinatorial methods of an explicit desingularization of X . This construction is explained in Section 5.3. Then we give a precise description of the rational form of the stringy motivic volume in terms of ω_X . In Section 6, we provide examples and applications. In particular, for a certain class of log terminal horospherical varieties of complexity one, we give a simple expression of another invariant called the *stringy Euler characteristic*; see Lemma 6.1. This allows us to rephrase, for this class, the smoothness condition in terms of the stringy Euler characteristic; see Theorem 6.4.

2. Arc spaces and motivic integration

Motivic integration was developed by Batyrev [Bat98] in the smooth case and by Denef and Loeser [DL99] in full generality. In this section, we recall main facts about this theory used throughout the paper (see also [Loo02, Loe09, Bli11] for survey articles).

2.1 The arc space of a variety

Let X be a variety. For any integer m , we denote by $\mathcal{L}_m(X)$ the m -jet scheme of arcs of X . It is a scheme of finite type, and for any field extension K of \mathbb{C} , its K -rational points are the $K[t]/(t^{m+1})$ -rational points of X . We will consider it with its reduced structure. For any $m \geq \ell \geq 0$, we denote by $j^{m,\ell}: \mathcal{L}_m(X) \rightarrow \mathcal{L}_\ell(X)$ the transition morphism induced by the Weil restriction morphism from $\mathbb{C}[t]/(t^{\ell+1})$ to $\mathbb{C}[t]/(t^{m+1})$. The *arc space* of X is the limit of the projective system $(\mathcal{L}_m(X), (j^{m,\ell}))$. It is a scheme, and for any field extension K of \mathbb{C} each K -rational point of $\mathcal{L}(X)$ corresponds to a unique $K[[t]]$ -rational point of X , and vice-versa. We write $\pi_\ell: \mathcal{L}(X) \rightarrow \mathcal{L}_\ell(X)$ for the natural truncation morphisms. They commute with the transition morphisms.

2.2 The Grothendieck ring $K_0(\mathbf{Var}_{\mathbb{C}})$

We denote by $[S] \in K_0(\mathbf{Var}_{\mathbb{C}})$ the class of an algebraic variety S and let $\mathbb{L} = [\mathbb{A}_{\mathbb{C}}^1]$. We write $\hat{\mathcal{M}}_{\mathbb{C}}$ for the completion of $K_0(\mathbf{Var}_{\mathbb{C}})[\mathbb{L}^{-1}]$ with respect to the usual filtration ensuring that $\mathbb{L}^{-n} \rightarrow 0$ (see [DL99, Bli11] and [NS11]).

2.3 Motivic integration

Let X be a smooth d -dimensional variety.

DEFINITION 2.1. A subset $C \subset \mathcal{L}(X)$ is a *cylinder* if $C = \pi_{m_0}^{-1}(\pi_{m_0}(C))$ for some m_0 and the set $\pi_{m_0}(C)$, called the m_0 -*basis* of C , is constructible in $\mathcal{L}_{m_0}(X)$. Note that $\mathcal{L}(X)$ itself is a cylinder (see [Gre66, Corollary 2]). The motivic measure of C is defined as

$$\mu_X(C) = [\pi_m(C)]\mathbb{L}^{-md} \quad \text{for any } m \geq m_0.$$

This does not depend on $m \geq m_0$ since if $m \geq \ell \geq 0$, the map $j^{m,\ell} |_{\pi_m(C)}: \pi_m(C) \rightarrow \pi_\ell(C)$ is a piecewise trivial fibration with fiber $\mathbb{A}^{(m-\ell)d}$.

Remark 2.2. A larger family of measurable sets can be considered (see [Bat98, DL99], [DL02, Appendix]). For instance, if $Y \subsetneq X$ is a closed, reduced subscheme, then $\mathcal{L}(Y)$ is measurable and $\mu_X(\mathcal{L}(Y)) = 0$ (see [DL99, Equation (3.2.2)] or [Bli11, Proposition 4,5]).

DEFINITION 2.3. A function $F: \mathcal{L}(X) \rightarrow \mathbb{Z} \cup \{\infty\}$ is *measurable* if for any $s \in \mathbb{Z} \cup \{\infty\}$, the subset $F^{-1}(s)$ is measurable. In that case, \mathbb{L}^{-F} is *integrable* over a measurable set C of $\mathcal{L}(X)$ if $\mu_X(F^{-1}(\infty)) = 0$ and the series $\sum_{s \in \mathbb{Z}} \mu_X(C \cap F^{-1}(s)) \mathbb{L}^{-s}$ converges in $\hat{\mathcal{M}}_{\mathbb{C}}$. Then, we let

$$\int_C \mathbb{L}^{-F} d\mu_X := \sum_{s \in \mathbb{Z}} \mu_X(C \cap F^{-1}(s)) \mathbb{L}^{-s}.$$

Example 2.4 ([Bli11, Section 2.4]). Let Y be a proper, closed subscheme of X defined by the sheaf of ideals \mathcal{I}_Y . Let γ be a point in $\mathcal{L}(X)$ and $\gamma^*: \mathcal{O}_X \rightarrow \mathcal{O}_{\text{Spec}(k_\gamma[[t]])}$ be its sheaf homomorphism. The *order of γ along Y* is $\text{ord}_Y(\gamma) := \sup\{e \in \mathbb{N} \cup \{\infty\} \mid \gamma^*(\mathcal{I}_Y) \subseteq (t^e)\}$. The function ord_Y is measurable, and the set $\text{ord}_Y^{-1}(\infty)$, equal to $\mathcal{L}(Y)$, has zero measure. Thus, for a divisor $D = \sum_{i=1}^s a_i D_i$ in X (where $a_i \in \mathbb{Q}$ and the D_i are prime divisors) and for an arc $\gamma \in \mathcal{L}(X)$, we set $\text{ord}_D(\gamma) = \sum_{i=1}^s a_i \text{ord}_{D_i}(\gamma)$ with value ∞ if one of the $\text{ord}_{D_i}(\gamma)$ is infinite. The function ord_D is then measurable.

2.4 Stringy invariants of varieties with log terminal singularities

Let X be an irreducible normal \mathbb{Q} -Gorenstein variety; namely, X is a normal variety and a (thus any) canonical divisor K_X is \mathbb{Q} -Cartier. We say that a morphism $f: X' \rightarrow X$ is a *resolution of singularities* if X' is smooth, f is birational and proper, and the exceptional locus is the union of finitely many normal crossings, irreducible, smooth divisors.

DEFINITION 2.5. Let X be a normal, \mathbb{Q} -Gorenstein algebraic variety with log terminal singularities. Let $f: X' \rightarrow X$ be a resolution of singularities of X , and let $(E_i)_{i \in I}$ be the set of irreducible components of its exceptional locus. Let K_X (respectively, $K_{X'}$) be a canonical divisor of X (respectively, X') and $(\nu_i)_{i \in I}$ be the multiplicities of the relative canonical divisor

$$K_{X'/X} := K_{X'} - f^*K_X = \sum_{i \in I} \nu_i E_i.$$

The *stringy motivic volume* $\mathcal{E}_{\text{st}}(X)$ is usually defined following [Bat98] as

$$\mathcal{E}_{\text{st}}(X) := \sum_{J \subset I} [E_J^\circ] \prod_{j \in J} \frac{\mathbb{L} - 1}{\mathbb{L}^{\nu_j + 1} - 1} \in \hat{\mathcal{M}}_{\mathbb{C}}(\mathbb{L}^{1/m}),$$

where m is the GCD of the denominators of the ν_i , the ring $\hat{\mathcal{M}}_{\mathbb{C}}(\mathbb{L}^{1/m})$ is defined as the localization and completion of $K_0(\mathbf{Var}_{\mathbb{C}})$ with respect to $\mathbb{L}^{1/m}$, and E_J° is $\bigcap_{j \in J} E_j \setminus \bigcup_{i \in I \setminus J} E_i$ for every subset J of I .

The theorem below follows from the appendix of [Bat98]; see also [DL02] and [Yas04].

THEOREM 2.6. *The stringy motivic volume is equal to*

$$\mathcal{E}_{\text{st}}(X) = \int_{\mathcal{L}(X')} \mathbb{L}^{-\text{ord}_{K_{X'/X}}} d\mu_{X'} \in \hat{\mathcal{M}}_{\mathbb{C}}(\mathbb{L}^{1/m})$$

and does not depend on the resolution $f: X' \rightarrow X$. If X is smooth, then $\mathcal{E}_{\text{st}}(X) = [X]$.

From $\mathcal{E}_{\text{st}}(X)$, we can deduce two new invariants for log terminal varieties. These invariants are defined by Batyrev [Bat98] and also studied by several authors such as Denef–Loeser [DL02], Yasuda [Yas04], and Schepers–Veys [Vey03, SV07].

DEFINITION 2.7. The *E-function* of a log terminal variety X is defined as

$$E_{\text{st}}(X; u, v) := \sum_{J \subset I} E(E_J; u, v) \prod_{j \in J} \frac{uv - 1}{(uv)^{\nu_j + 1} - 1},$$

where for any variety V , the invariant $E(V; u, v)$ is the usual Hodge–Deligne polynomial of V in the variables u and v . The *stringy Euler characteristic* of X is

$$e_{\text{st}}(X) := \sum_{J \subset I} e(E_J) \prod_{j \in J} \frac{1}{\nu_j + 1},$$

where $e(E_J) = E(E_J; 1, 1)$ denotes the usual Euler characteristic.

3. Horospherical actions

Throughout, let G be a connected, simply connected, reductive algebraic group over \mathbb{C} with Borel subgroup B , maximal torus Q , and maximal unipotent subgroup U such that $B = QU$.

3.1 Horospherical transformations

A (G/H) -embedding of a horospherical homogeneous space G/H is a pair (X, x) such that X is a normal G -variety containing x , the orbit $G \cdot x$ of x is open, and the stabilizer G_x of x is H . For brevity, we denote such an embedding simply by X . The subgroup H is called a *horospherical subgroup*.

Description of horospherical subgroups of G . Let Φ be the set of simple roots of G and $W = N_G(Q)/Q$ be the Weyl group of G . We denote by $s_\alpha \in W$ the simple reflection associated with $\alpha \in \Phi$ and by \dot{s}_α a lift of s_α to G . We also denote by w_0 the longest element of W . If $I \subset \Phi$, we set $\dot{W}_I := \langle \dot{s}_\alpha \mid \alpha \in I \rangle$, and we let P_I be the parabolic subgroup generated by B and \dot{W}_I . The map $I \mapsto P_I$ between subsets of Φ and closed subgroups of G containing B is bijective.

By [Pas08, Proposition 2.4], there is a bijection between subgroups H of G containing U and pairs (M, I) , where M is a sublattice of the character group $\mathbb{X}(Q)$ and $I \subset \Phi$, subject to the property that for any $\alpha \in I$, the associated coroot α^\vee satisfies $\langle m, \alpha^\vee \rangle = 0$ for any $m \in M$. The bijection is constructed as follows. First, consider the normalizer $N_G(H)$ of H in the group G . It is a parabolic subgroup $P = P_I$, where $I \subset \Phi$. The subset I constitutes the first part of the data. Now the quotient $T := P/H$ is a torus, and our second datum M is the character lattice of T .

Colors and charts. Let Y be a horospherical G -variety of arbitrary complexity and $L \subset G$ be a closed subgroup of G . An *L-divisor* is an L -stable prime divisor, and a *color* is a B -divisor which is not G -stable.

A *B-chart* of Y is a dense, open, B -stable, affine subset of Y . We say that the horospherical variety Y is *simple* if Y possesses a B -chart which intersects every G -orbit of Y . Since Y is normal, it is the union of simple, G -stable, open subsets; see [Sum74, Theorem 1] and [Kno91, Theorem 1.3]. Moreover, every normal, simple, horospherical G -variety is quasi-projective.

Models. Let Y be a variety with a horospherical G -action. We say that a G -variety Z is a *model* of Y if Z is normal and there exists a G -equivariant birational map $Z \dashrightarrow Y$. For instance, any horospherical G -variety Y has a model of the form $C \times G/H$, where H is a horospherical subgroup of G , the factor C is a smooth variety, and G acts by left multiplication on G/H and trivially on C (see [Tim11, Proposition 7.7]). This implies that the dimension of C is equal to the complexity of the action of G on Y .

Let Y be a horospherical G -variety with model $Z = C \times G/H$. The variety Y contains a G -stable, open subset which is identified with $\Gamma \times G/H \subset Z$, where $\Gamma \subset C$ is open dense. Let (M, I) be the lattice/subset pair parametrizing H . With any $\alpha \in \Phi \setminus I$, we associate a color by letting D_α denote the set $\Gamma \times p^{-1}(X_\alpha) \subset Y$, where $p: G/H \rightarrow G/P$ is the natural projection, $P = N_G(H)$, and X_α is the corresponding Schubert variety. The map $\alpha \mapsto D_\alpha$ between $\Phi \setminus I$ and the set \mathcal{F}_Y of colors of Y is bijective; see [FMSS95, Lemma 3]. We will use the same notation D_α for the colors of G/H and the colors of Y .

3.2 Colored polyhedral divisors

In this subsection, we consider horospherical varieties of complexity one, which as we have seen are G -equivariantly birational to direct products $Z = C \times G/H$, where C is a smooth projective curve and H is a horospherical subgroup of G . Here, we introduce some combinatorial data which describes all the models of Z . We refer to [Tim11, Section 16].

Let (M, I) be the pair associated with the horospherical subgroup H and N be the dual lattice $\text{Hom}(M, \mathbb{Z})$. Denote by $M_{\mathbb{Q}}$ and $N_{\mathbb{Q}}$ the dual associated vector spaces $\mathbb{Q} \otimes_{\mathbb{Z}} M$ and $\mathbb{Q} \otimes_{\mathbb{Z}} N$. The dual $\sigma^\vee \subset M_{\mathbb{Q}}$ of a polyhedral cone $\sigma \subset N_{\mathbb{Q}}$ is

$$\sigma^\vee = \{m \in M_{\mathbb{Q}} \mid \forall v \in \sigma, \langle m, v \rangle \geq 0\}.$$

The polyhedral cone σ is *strongly convex* (that is, $\{0\}$ is a face of σ) if and only if σ^\vee generates $M_{\mathbb{Q}}$.

DEFINITION 3.1 ([AH06]). Let σ be a strongly convex polyhedral cone in $N_{\mathbb{Q}}$ and C_0 be a smooth curve.

- (i) A σ -polyhedral divisor on C_0 is a formal sum

$$\mathfrak{D} = \sum_{y \in C_0} \Delta_y \cdot [y],$$

where $\Delta_y \subset N_{\mathbb{Q}}$ is a σ -polyhedron (that is, the Minkowski sum of the cone σ and a non-empty polytope $\Pi \subset N_{\mathbb{Q}}$) with the property that $\Delta_y = \sigma$ for all but finitely many $y \in C_0$. The set of special points of \mathfrak{D} is $\text{Sp}(\mathfrak{D}) := \{y \in C_0 \mid \Delta_y \neq \sigma\}$. The cone σ is called the *tail* of \mathfrak{D} , and the curve C_0 is its *locus*.

- (ii) The *degree* of \mathfrak{D} is defined, if C_0 is complete, as the Minkowski sum $\text{deg } \mathfrak{D} := \sum_{y \in C_0} \Delta_y$ inside $N_{\mathbb{Q}}$, and as the empty set otherwise.
- (iii) For $m \in \sigma^\vee$, we define a \mathbb{Q} -divisor on C_0 , called the *evaluation of \mathfrak{D} at m* , by setting

$$\mathfrak{D}(m) := \sum_{y \in C_0} \min\{\langle m, v \rangle \mid v \in \Delta_y\} \cdot [y].$$

DEFINITION 3.2. (i) For any subsemigroup S of M , we let $\mathbb{C}[S] = \bigoplus_{m \in S} \mathbb{C}\chi^m$ be the \mathbb{C} -algebra subject to the relations $\chi^m \cdot \chi^{m'} = \chi^{m+m'}$ for all $m, m' \in S$.

(ii) Let \mathfrak{D} be a polyhedral divisor. The *associated M -graded algebra* of \mathfrak{D} is the subalgebra

$$A(C_0, \mathfrak{D}) := \bigoplus_{m \in \sigma^\vee \cap M} H^0(C_0, \mathcal{O}_{C_0}([\mathfrak{D}(m)])) \otimes \chi^m \subset \mathbb{C}(C_0) \otimes_{\mathbb{C}} \mathbb{C}[M],$$

where $[\mathfrak{D}(m)]$ is obtained by taking the integral part of the coefficients of $\mathfrak{D}(m)$.

DEFINITION 3.3. A σ -polyhedral divisor \mathfrak{D} is *proper* if either C_0 is affine, or it is projective and the two following conditions are satisfied:

- (i) $\deg \mathfrak{D} \subsetneq \sigma$.
- (ii) If $\min\{\langle m, v \rangle \mid v \in \deg \mathfrak{D}\} = 0$ for some $m \in \sigma^\vee$, then $\mathfrak{D}(rm)$ is principal for some $r \in \mathbb{Z}_{>0}$.

If \mathfrak{D} is proper, then $A(C_0, \mathfrak{D})$ and $\mathbb{C}(C_0) \otimes_{\mathbb{C}} \mathbb{C}[M]$ have the same field of fractions.

The next definition introduces the *coloration map* ϱ of the horospherical homogeneous space G/H .

DEFINITION 3.4. Let (M, I) be the lattice/subset pair associated with the horospherical subgroup H . For any color D of G/H , there exists a unique root $\alpha \in \Phi$ such that $D = D_\alpha$. In particular, the coroot α^\vee is an element of $\text{Hom}(\mathbb{X}(Q), \mathbb{Z})$. Thus, its restriction $\alpha^\vee|_M: M \rightarrow \mathbb{Z}$ to M is an element of $N = \text{Hom}(M, \mathbb{Z})$, and we define $\varrho(D)$ as $\alpha^\vee|_M$.

DEFINITION 3.5. A pair $(\mathfrak{D}, \mathcal{F})$ is a *colored σ -polyhedral divisor* (see [LT16, Section 1.3]) on C_0 if \mathcal{F} is a subset of $\mathcal{F}_{G/H}$ such that $\varrho(\mathcal{F}) \subset \sigma$ and $0 \notin \varrho(\mathcal{F})$ and if \mathfrak{D} is a proper σ -polyhedral divisor on C_0 .

We now give a combinatorial description of the simple models of the product $C \times G/H$, which follows from a general classification result for normal G -varieties of complexity one; see [Tim97, Theorem 3.1].

THEOREM 3.6. *Let G be a connected, simply connected, reductive algebraic group and H be a horospherical subgroup associated with a lattice/subset pair (M, I) . Define $Z := C \times G/H$, where C is a smooth projective curve.*

- (i) *Let $(\mathfrak{D}, \mathcal{F})$ be a colored polyhedral divisor on an open, dense subset $C_0 \subset C$. Then there exists a simple G -model $X(\mathfrak{D}) := X(\mathfrak{D}, \mathcal{F})$ of Z containing a B -chart which is determined by $(\mathfrak{D}, \mathcal{F})$. The construction of $X(\mathfrak{D})$ will be specified in equation (3.2).*
- (ii) *Let X be a simple G -model of Z . Then there exist an open, dense subset $C_0 \subset C$, a colored polyhedral divisor $(\mathfrak{D}, \mathcal{F})$ on C_0 , and a G -isomorphism $X \rightarrow X(\mathfrak{D})$.*

Let us sketch the construction of the G -variety $X(\mathfrak{D})$ from item (i). Denote by $P_{\mathcal{F}}$ the parabolic subgroup of G containing the Borel subgroup B and corresponding to the set of roots

$$I_{\mathcal{F}} = \{\alpha \in \Phi \setminus I \mid D_\alpha \in \mathcal{F}\} \cup I.$$

Let L be the Levi subgroup of $P_{\mathcal{F}}$ containing the maximal torus Q and B_L be the Borel subgroup of L containing Q , so that $I_{\mathcal{F}}$ is the set of simple roots of L . We also write $H_L := H \cap L$ and $U_L := U \cap L$. The subgroup H_L contains U_L ; hence, the homogeneous space L/H_L is horospherical. It is quasi-affine; see [Tim11, Corollary 15.6]. Note that L/H_L is constructed so that the set of B -divisors in L/H_L exactly identifies with \mathcal{F} . Moreover, the lattice of B_L -weights in $\mathbb{C}(L/H_L)$ is the lattice M .

Denote by $\mathbb{X}_+(Q) \subset M_{\mathbb{Q}}$ the cone generated by the dominant weights of $\mathbb{C}[L/H_L]$. Recall that the rational L -module $\mathbb{C}[L/H_L]$ admits a \mathbb{C} -algebra graduation

$$\mathbb{C}[L/H_L] = \bigoplus_{m \in \mathbb{X}_+(Q) \cap M} V(m),$$

where $V(m)$ denotes the irreducible rational representation corresponding to $m \in \mathbb{X}_+(Q) \cap M$ (see [Tim11, Proposition 7.6]).

Since by the definition of $(\mathfrak{D}, \mathcal{F})$, we have $\varrho(\mathcal{F}) \subset \sigma$, it follows that $\sigma^\vee \subset \mathbb{X}_+(Q)$. Thus, we may define a subalgebra of $\mathbb{C}(C) \otimes_{\mathbb{C}} \mathbb{C}[L/H_L]$ by

$$A(C_0, \mathfrak{D}, \mathcal{F}) := \bigoplus_{m \in \sigma^\vee \cap M} H^0(C_0, \mathcal{O}_{C_0}([\mathfrak{D}(m)])) \otimes_{\mathbb{C}} V(m). \quad (3.1)$$

Set $Y(\mathfrak{D}, \mathcal{F}) := \text{Spec } A(C_0, \mathfrak{D}, \mathcal{F})$. Since \mathfrak{D} is proper, $Y(\mathfrak{D}, \mathcal{F})$ is a well-defined affine L -model of the product $C \times L/H_L$. To conclude, consider the parabolic induction

$$X(\mathfrak{D}) = X(\mathfrak{D}, \mathcal{F}) := G \times^{P_{\mathcal{F}}} Y(\mathfrak{D}, \mathcal{F}). \quad (3.2)$$

The notation $G \times^{P_{\mathcal{F}}} Y(\mathfrak{D}, \mathcal{F})$ means that $X(\mathfrak{D})$ is the quotient $(G \times Y(\mathfrak{D}, \mathcal{F}))/P_{\mathcal{F}}$, where $P_{\mathcal{F}}$ acts by $p \cdot (g, y) := (gp^{-1}, \phi(p) \cdot y)$ for all $p \in P_{\mathcal{F}}$, $g \in G$, and $y \in Y(\mathfrak{D}, \mathcal{F})$. Here $\phi: P_{\mathcal{F}} \rightarrow L$ is the usual projection. Note that $X(\mathfrak{D})$ is a fiber bundle over $G/P_{\mathcal{F}}$ with fiber $Y(\mathfrak{D}, \mathcal{F})$.

The original construction of the simple G -models $X(\mathfrak{D})$ from [Tim97] generalized the approach of [Kno91] in complexity one. Let us recall here how this construction relates to the one explained above.

DEFINITION 3.7. Let Y be a horospherical G -variety. A *locality* of $\mathbb{C}(Y)$ is a local ring $R_{\mathfrak{p}}$, where $\mathfrak{p} \subset R$ is a prime ideal in a subalgebra R of $\mathbb{C}(Y)$ of finite type with fraction field $\mathbb{C}(Y)$. The set of localities $\mathfrak{S}(Y)$ is naturally endowed with a \mathbb{C} -scheme structure; it is called the *scheme of geometric localities*. We denote by $\mathfrak{S}_G(Y) \subset \mathfrak{S}(Y)$ the maximal normal, open subset where the G -action (induced by the G -action on $\mathbb{C}(Y)$) is a morphism of \mathbb{C} -schemes; we will call it the *equivariant scheme of geometric localities*.

According to the previous definition, a G -model of a horospherical G -variety Y is nothing but a G -stable, separated, open, dense subset of $\mathfrak{S}_G(Y)$ which is also of finite type over \mathbb{C} .

Now consider a horospherical G -variety of the form $Z = C \times G/H$, where C is a smooth projective curve and H is a horospherical subgroup.

DEFINITION 3.8. The *hyperspace* $\mathcal{N}_{\mathbb{Q}}$ is the set $C \times N_{\mathbb{Q}} \times \mathbb{Q}_{\geq 0}$ modulo the equivalence relation

$$(y, \nu, \ell) \sim (y', \nu', \ell') \Leftrightarrow (y = y', \nu = \nu', \ell = \ell') \text{ or } (\ell = \ell' = 0, \nu = \nu').$$

Since an element $(y, \nu, 0) \in \mathcal{N}_{\mathbb{Q}}$ does not depend on $y \in C$, from now on, we will denote it by $(C, \nu, 0)$. We also write $\mathcal{N} \subset \mathcal{N}_{\mathbb{Q}}$ for the subset of integral points

$$\mathcal{N} = \{(y, \nu, \ell) \in \mathcal{N}_{\mathbb{Q}} \mid \nu \in N, \ell \in \mathbb{Z}_{\geq 0}\}.$$

Let $\mathfrak{D} = \sum_{y \in C_0} \Delta_y \cdot [y]$ be a σ -polyhedral divisor on an open dense subset $C_0 \subset C$. For $y \in C_0$, the *Cayley cone* $C_y(\mathfrak{D})$ is defined as the cone generated by the subsets $\sigma \times \{0\}$ and $\Delta_y \times \{1\}$ in $N_{\mathbb{Q}} \times \mathbb{Q}_{\geq 0}$. The *hypercone* associated with \mathfrak{D} is the subset $C(\mathfrak{D}) \subset \mathcal{N}_{\mathbb{Q}}$ defined by

$$C(\mathfrak{D}) = \bigcup_{y \in C_0} \{y\} \times C_y(\mathfrak{D}) / \sim.$$

We denote by $C(\mathfrak{D})(1)$ the subset of elements $[y, \nu, \ell] \in C(\mathfrak{D}) \cap \mathcal{N}$ such that (ν, ℓ) is an integral primitive generator of a one-dimensional face of $C_y(\mathfrak{D})$.

Each triple $\xi = (y, \nu, \ell) \in \mathcal{N}_{\mathbb{Q}}$ induces a unique discrete, G -invariant valuation $w(\xi): \mathbb{C}(Z)^* \rightarrow \mathbb{Q}$, whose restriction to the subalgebra $\mathbb{C}(C) \otimes_{\mathbb{C}} \mathbb{C}[M] \subset \mathbb{C}(Z)$ satisfies

$$w(\xi)(f \otimes \chi^m) = \ell \operatorname{ord}_y(f) + \langle m, \nu \rangle$$

for all $f \in \mathbb{C}(C)^*$ and $m \in M$. Here we identify the algebra $\mathbb{C}[M]$ with $\mathbb{C}[Bx_0]^U$, where Bx_0 is the open B -orbit in G/H . From this description, it follows that the set of G -invariant discrete valuations of $\mathbb{C}(Z)$ with values in \mathbb{Q} is in one-to-one correspondence with the hyperspace $\mathcal{N}_{\mathbb{Q}}$ (see [Tim11, Corollary 19.13, Theorems 20.3 and 21.10]).

Let us now consider the morphism $X(\mathfrak{D}) \rightarrow G/P_{\mathcal{F}}$ induced by projecting on the first factor in equation (3.2); its fibers are isomorphic to $Y(\mathfrak{D}, \mathcal{F})$. The inverse image of the open B -orbit By_0 of $G/P_{\mathcal{F}}$ is a B -chart, which we denote by X_0 . This B -chart intersects all the G -orbits in $X(\mathfrak{D})$. Note that By_0 is isomorphic to the affine space $\mathbb{A}_{\mathbb{C}}^r$, where $r = \dim G/P_{\mathcal{F}}$. Since the fibration restricted to By_0 is trivial, the chart X_0 is identified with $Y(\mathfrak{D}, \mathcal{F}) \times \mathbb{A}_{\mathbb{C}}^r$. The ring of functions on X_0 can be described as

$$\mathbb{C}[X_0] = (\mathbb{C}(C) \otimes_{\mathbb{C}} \mathbb{C}[Bx_0]) \cap \bigcap_{\xi \in \mathcal{C}(\mathfrak{D})(1)} \mathcal{O}_{v(\xi)} \cap \bigcap_{D \in \mathcal{F}} \mathcal{O}_{v_D}, \quad (3.3)$$

where v_D is the valuation associated with the divisor $D \in \mathcal{F}$ and \mathcal{O}_{v_D} and $\mathcal{O}_{v(\xi)}$ are the respective valuation rings of v_D and $v(\xi)$.

Remark 3.9. The variety $X(\mathfrak{D})$ is a union of G -orbits

$$X(\mathfrak{D}) = G \cdot X_0 = \{g \cdot x \mid g \in G, x \in X_0\} \subset \mathfrak{S}_G(Z). \quad (3.4)$$

Thus, equations (3.3) and (3.4) yield another more conceptual construction of the G -variety $X(\mathfrak{D})$; see [Tim11, Section 16]. From now on, we identify $X(\mathfrak{D})$ with an open subset of $\mathfrak{S}_G(Z)$.

3.3 Colored divisorial fans

Here we introduce the combinatorial objects describing horospherical G -varieties of complexity one. The idea is to consider “fans of colored polyhedral divisors” in order to describe these varieties as a gluing of simple G -models.

DEFINITION 3.10 ([LT16, Section 1.3.4]). Let C be a smooth projective curve and G/H be a horospherical homogeneous space. A *colored divisorial fan* on the pair $(C, G/H)$ is a finite set $\mathcal{E} = \{(\mathfrak{D}^i, \mathcal{F}^i) \mid i \in J\}$ of colored polyhedral divisors, where

$$\mathfrak{D}^i = \sum_{y \in C^i} \Delta_y^i \cdot [y].$$

Here C^i is an open dense subset of C , we have $\mathcal{F}^i \subset \mathcal{F}_{G/H}$, and \mathfrak{D}^i and \mathcal{F}^i are subject to the following conditions:

- (i) For all $i, j \in J$, we have $(\mathfrak{D}^i \cap \mathfrak{D}^j, \mathcal{F}^i \cap \mathcal{F}^j) \in \mathcal{E}$, where the intersection is given by

$$\mathfrak{D}^i \cap \mathfrak{D}^j := \sum_{y \in C_{i,j}} (\Delta_y^i \cap \Delta_y^j) \cdot [y]$$

and the curve $C_{i,j}$ by the equality $C_{i,j} := \{y \in C^i \cap C^j \mid \Delta_y^i \cap \Delta_y^j \neq \emptyset\}$.

- (ii) For all $i, j \in J$ and $y \in C_{i,j}$, the polyhedron $\Delta_y^i \cap \Delta_y^j$ is a common face to Δ_y^i and Δ_y^j .
 (iii) For all $i, j \in J$, we have

$$\mathcal{F}^i \cap \mathcal{F}^j = \varrho^{-1}(\sigma_i \cap \sigma_j) \cap \mathcal{F}^i = \varrho^{-1}(\sigma_i \cap \sigma_j) \cap \mathcal{F}^j,$$

where σ_i and σ_j are the respective tails of \mathfrak{D}^i and \mathfrak{D}^j .

- (iv) The intersection of the degree of \mathfrak{D}^i with the tail σ_{ij} of $\mathfrak{D}^i \cap \mathfrak{D}^j$ is equal to the intersection of the degree of \mathfrak{D}^j with σ_{ij} .

To any colored divisorial fan \mathcal{E} , one can attach some combinatorial objects as follows.

DEFINITION 3.11. The set

$$H(\mathcal{E}) := \{(C(\mathfrak{D}), \mathcal{F}) \mid (\mathfrak{D}, \mathcal{F}) \in \mathcal{E}\}$$

is the associated *colored hyperfan* (see [Tim11, Definition 16.18]). The *support* of \mathcal{E} is defined as

$$|\mathcal{E}| := \bigcup_{(\mathfrak{D}, \mathcal{F}) \in \mathcal{E}} C(\mathfrak{D}) \subset \mathcal{N}_{\mathbb{Q}}$$

and the *set of special points* as

$$\mathrm{Sp}(\mathcal{E}) := \bigcup_{(\mathfrak{D}, \mathcal{F}) \in \mathcal{E}} \mathrm{Sp}(\mathfrak{D}).$$

We refer to Definition 3.1 for $\mathrm{Sp}(\mathfrak{D})$. The *tail fan* of \mathcal{E} is the fan $\Sigma(\mathcal{E})$ generated by all the tails σ of polyhedral divisors \mathfrak{D} with $(\mathfrak{D}, \mathcal{F}) \in \mathcal{E}$.

When $G = T$ is a torus, we write $\mathcal{E} = \{\mathfrak{D}^i \mid i \in J\}$ instead of $\mathcal{E} = \{(\mathfrak{D}^i, \emptyset) \mid i \in J\}$, and we recover the usual divisorial fans of [AHS08, Definition 5.2]. The following result provides a full description of horospherical varieties of complexity one.

THEOREM 3.12 ([Tim11, Theorems 12.13 and 16.19]). *Let C be a smooth projective curve, G/H be a horospherical homogeneous space, and Z be the product $C \times G/H$. Denote by \mathcal{E} a colored divisorial fan on $(C, G/H)$. Then the open union*

$$X(\mathcal{E}) := \bigcup_{(\mathfrak{D}, \mathcal{F}) \in \mathcal{E}} X(\mathfrak{D}, \mathcal{F})$$

inside the equivariant scheme of geometric localities $\mathfrak{S}_G(Z)$ is a G -model of Z . Conversely, every G -model of Z arises in this way. Moreover, $X(\mathcal{E})$ is a complete variety if and only if $|\mathcal{E}| = \mathcal{N}_{\mathbb{Q}}$.

Let us now recall the construction of the discoloration morphism associated with a colored divisorial fan from [LT16, Section 2.2]. This construction will allow us to provide specific equivariant desingularizations of $X(\mathcal{E})$. If \mathcal{E} is a colored divisorial fan, we denote by

$$\mathcal{E}_{\mathrm{dis}} := \{(\mathfrak{D}, \emptyset) \mid (\mathfrak{D}, \mathcal{F}) \in \mathcal{E}\}$$

its *discoloration*, that is, the colored divisorial fan obtained from \mathcal{E} by removing the colors. For any $(\mathfrak{D}, \mathcal{F})$ in \mathcal{E} (respectively, $(\mathfrak{D}, \emptyset)$ in $\mathcal{E}_{\mathrm{dis}}$) we consider X_0 (respectively, X_{dis}), the B -chart associated with $(\mathfrak{D}, \mathcal{F})$ (respectively, with $(\mathfrak{D}, \emptyset)$). The inclusions of \mathbb{C} -algebras $\mathbb{C}[X_0] \subset \mathbb{C}[X_{\mathrm{dis}}]$ induce morphisms $X(\mathfrak{D}, \emptyset) \rightarrow X(\mathfrak{D}, \mathcal{F})$ which glue into a birational proper G -equivariant morphism

$$\pi_{\mathrm{dis}}: X(\mathcal{E}_{\mathrm{dis}}) \rightarrow X(\mathcal{E}). \tag{3.5}$$

Writing $P = P_I = N_G(H)$, $T = P/H$, and $M = \mathbb{X}(T)$, we define the T -variety associated with \mathcal{E} :

$$V(\mathcal{E}) := \bigcup_{i \in J} \mathrm{Spec} A(C^i, \mathfrak{D}^i) \subset \mathfrak{S}_T(C \times T), \tag{3.6}$$

where $\mathfrak{S}_T(C \times T)$ is the T -equivariant scheme of geometric localities of $C \times T$ and $A(C^i, \mathfrak{D}^i)$ denotes the M -graded algebra associated with \mathfrak{D}^i ; see Definition 3.2. From [LT16, Proposition 2.9], it follows that $X(\mathcal{E}_{\text{dis}})$ is G -isomorphic to $G \times^P V(\mathcal{E})$, where P acts on $V(\mathcal{E})$ via the canonical surjection $P \rightarrow T$.

4. The arc space of a horospherical variety of complexity one

In this section, we describe the arc space of a horospherical variety X of complexity one, in order to compute its stringy E -function via motivic integration in Section 5.

Let K be a field extension of \mathbb{C} and $\mathcal{O} := \mathcal{O}_K$ and $\mathcal{K} := \mathcal{K}_K$ be the corresponding ring of power series and its fraction field. Denote by 0 and η the closed and generic point of $\text{Spec } \mathcal{O}_K$, respectively. Our goal is to describe the set of K -valued points of $\mathcal{L}(X)$, that is, the set $X(\mathcal{O}_K)$. To do this, we restrict ourselves to the study of a subset $\mathcal{L}_\Gamma(X)$ of $\mathcal{L}(X)$ which has the same motivic measure as $\mathcal{L}(X)$, and we decompose it into *horizontal* and *vertical arcs*; see Sections 4.1 and 4.2 for the case of T -varieties of complexity one. We give a parametrization of the $G(\mathcal{O})$ -orbits in Theorem 4.12. Finally, in Section 4.4, we show that the corresponding pieces in $\mathcal{L}_\Gamma(X)$ are cylinders, hence measurable, and we compute their motivic measure in Theorem 4.16.

Notation 4.1. We keep the same notation $M, N, C, G/H, \mathcal{E}, \dots$ as in the previous section for describing a horospherical variety $X = X(\mathcal{E})$ of complexity one. In particular, for the colored divisorial fan $\mathcal{E} = \{(\mathfrak{D}^i, \mathcal{F}^i)\}_{i \in J}$ and for any $i \in J$, we write

$$\mathfrak{D}^i = \sum_{y \in C^i} \Delta_y^i \cdot [y],$$

where $C^i \subset C$ is open dense. The symbol σ_i denotes the tail of \mathfrak{D}^i , and Γ is an open, dense, affine subset of C which does not intersect $\text{Sp}(\mathcal{E})$.

4.1 Horizontal and vertical arcs

In this subsection, we also assume that $G = T$ is a torus, that $H = \{e\}$ is trivial, and that \mathcal{E} consists of a single colored divisor \mathfrak{D} with tail σ and *affine locus* C_0 containing Γ . The construction following Theorem 3.6 shows that X is the T -variety $\text{Spec } A(C_0, \mathfrak{D})$.

Let X_σ be the toric variety $\text{Spec } \mathbb{C}[\sigma^\vee \cap M]$ associated with the cone σ . The product $\Gamma \times X_\sigma$ is a dense, open, T -stable subset of X , and so is its subset $\Gamma \times T$. Define

$$X_\Gamma = X_\Gamma^K := X(\mathcal{O}) \cap (\Gamma \times T)(\mathcal{K}) := \{\alpha : \text{Spec } \mathcal{O}_K \rightarrow X \mid \alpha(\eta) \in \Gamma \times T\} \subset X(\mathcal{O}),$$

where $X(\mathcal{O})$ and $(\Gamma \times T)(\mathcal{K})$ are both viewed as subsets of $X(\mathcal{K})$.

Remark 4.2. The subspace

$$\mathcal{L}_\Gamma(X) := \{\alpha \in \mathcal{L}(X) \mid \tilde{\alpha}(\eta) \in \Gamma \times T\}$$

has the same motivic measure as $\mathcal{L}(X)$. Indeed, its complement in $\mathcal{L}(X)$ identifies with the arc space of $X_1 := X \setminus (\Gamma \times T)$, which has zero measure; see Remark 2.2. Hence for purposes of motivic integration, we may study $\mathcal{L}_\Gamma(X)$ instead of the whole arc space $\mathcal{L}(X)$. Clearly, $\mathcal{L}_\Gamma(X)(K) = X_\Gamma^K$.

Any K -valued arc α in $\mathcal{L}_\Gamma(X)(K)$ induces morphisms $\mathbb{C}[M] \rightarrow \mathcal{K}$ and $\mathbb{C}[\Gamma] \rightarrow \mathcal{K}$. Indeed, as $\Gamma \times T$ is an open subset of X , we have a commutative diagram

$$\begin{array}{ccc}
 \mathbb{C}[\Gamma] \otimes_{\mathbb{C}} \mathbb{C}[M] & \xrightarrow{\bar{\alpha}^*} & \mathcal{K} \\
 \uparrow & & \uparrow \\
 \mathbb{C}[X] & \xrightarrow{\alpha^*} & \mathcal{O}.
 \end{array}$$

We denote by α_{Γ}^* (respectively, by α_M^*) the restriction of $\bar{\alpha}^*$ to $\mathbb{C}[\Gamma]$ (respectively, to $\mathbb{C}[M]$). Clearly, α is uniquely determined by the data α_{Γ}^* and α_M^* . Conversely, if we are given two \mathbb{C} -algebra morphisms $\beta_{\Gamma}: \mathbb{C}[\Gamma] \rightarrow \mathcal{K}$ and $\beta_M: \mathbb{C}[M] \rightarrow \mathcal{K}$ such that $\beta_{\Gamma} \otimes \beta_M(\mathbb{C}[X]) \subset \mathcal{O}$, then there exists an arc $\alpha \in X_{\Gamma}$ such that $\alpha_{\Gamma}^* = \beta_{\Gamma}$ and $\alpha_M^* = \beta_M$.

Remark 4.3. Following [Ish04, Proof of Theorem 4.1], if $\alpha \in X_{\Gamma}$, we parametrize the map α_M^* using the group homomorphisms $\nu_{\alpha}: M \rightarrow \mathbb{Z}$ and $\omega_{\alpha}: M \rightarrow \mathcal{O}^*$ defined by the equality $\alpha_M^*(\chi^m) = t^{\langle m, \nu_{\alpha} \rangle} \omega_{\alpha}(m)$ for any $m \in M$. We also parametrize α_{Γ}^* using the valuation $v_{\alpha}: \mathbb{C}[\Gamma] \rightarrow \mathbb{Z}$ and the function $R_{\alpha}: \mathbb{C}[\Gamma] \rightarrow \mathcal{O}^*$ such that $\alpha_{\Gamma}^*(f) = t^{v_{\alpha}(f)} R_{\alpha}(f)$. Since $\mathbb{C}(\Gamma)$ is of transcendence degree one over \mathbb{C} , there exist unique $\ell_{\alpha} \in \mathbb{Z}_{\geq 0}$ and $y_{\alpha} \in \bar{\Gamma} = C$ such that $v_{\alpha} = \ell_{\alpha} \text{ord}_{y_{\alpha}}$.

The following lemma is a direct consequence of the classification of invariant valuations in [Tim11, Section 16] for toric varieties of complexity one.

LEMMA 4.4. *Let $w: \mathbb{C}(X)^* \rightarrow \mathbb{Q}$ be a T -invariant discrete valuation. The following statements are equivalent:*

- (i) *The restriction $w|_{\mathbb{C}[X] \setminus \{0\}}$ is non-negative.*
- (ii) *There exists a triple $(y, \nu, \ell) \in C(\mathfrak{D})$ such that for any homogeneous element $f \otimes \chi^m$ in $\mathbb{C}[X]$, we have $w(f \otimes \chi^m) = \ell \text{ord}_y(f) + \langle m, \nu \rangle$.*

Hence if $\alpha \in X_{\Gamma}$ is an arc, then the triple $(y_{\alpha}, \nu_{\alpha}, \ell_{\alpha})$ defined above is a point of the hypercone $C(\mathfrak{D}) \cap \mathcal{N}$.

The following disjoint subsets of X_{Γ} are defined according to the position of the image of $0 \in \text{Spec } \mathcal{O}$.

DEFINITION 4.5. Define the *horizontal part* of X_{Γ} by

$$\mathcal{X}_{\text{hor}} := \{\alpha: \text{Spec } \mathcal{O} \rightarrow X \mid \alpha(0) \in \Gamma \times X_{\sigma} \text{ and } \alpha(\eta) \in \Gamma \times T\}$$

and its *vertical part* by $\mathcal{X}_{\text{ver}} := X_{\Gamma} \setminus \mathcal{X}_{\text{hor}}$, that is,

$$\mathcal{X}_{\text{ver}} = \{\alpha: \text{Spec } \mathcal{O} \rightarrow X \mid \alpha(0) \notin \Gamma \times X_{\sigma} \text{ and } \alpha(\eta) \in \Gamma \times T\}.$$

The condition $\alpha(0) \notin \Gamma \times X_{\sigma}$ means that the closed point $\alpha(0)$ belongs to the fiber of the quotient map $X \rightarrow C_0$ over a point of $C_0 \setminus \Gamma$.

We may characterize elements $\alpha \in \mathcal{X}_{\text{ver}}$ in terms of their associated maps α_{Γ}^* .

LEMMA 4.6. *Let $\alpha \in X_{\Gamma}$ be an arc. The following properties are equivalent:*

- (i) $\alpha \in \mathcal{X}_{\text{ver}}$.
- (ii) $\alpha_{\Gamma}^*(\mathbb{C}[\Gamma]) \not\subset \mathcal{O}$.
- (iii) *We have $y_{\alpha} \in C_0 \setminus \Gamma$ and $\ell_{\alpha} \neq 0$, where y_{α} and ℓ_{α} are as in Remark 4.3.*

In particular, if one of the above conditions is satisfied, then α_{Γ}^ is injective.*

Proof. The equivalence between statements (ii) and (iii) is clear. Let us now prove that statements (i) and (iii) are equivalent.

If $y_\alpha \in \Gamma$, then $\nu_\alpha \in \sigma \cap N$ by the definition of $C(\mathfrak{D})$. Moreover, ord_{y_α} is non-negative on $\mathbb{C}[\Gamma]$, and the image of $\mathbb{C}[\Gamma] \otimes_{\mathbb{C}} \mathbb{C}[X_\sigma]$ by $\alpha_\Gamma^* \otimes \alpha_M^*$ is contained in \mathcal{O} ; hence $\alpha \in \mathcal{X}_{\text{hor}}$. So $\alpha \in \mathcal{X}_{\text{ver}}$ implies $y_\alpha \in C_0 \setminus \Gamma$. Conversely, if $y_\alpha \in C_0 \setminus \Gamma$ and $\ell_\alpha \neq 0$, then there exists an $f \in \mathbb{C}[\Gamma]$ such that $\ell_\alpha \text{ord}_{y_\alpha}(f) < 0$, so that $\alpha_\Gamma^*(\mathbb{C}[\Gamma]) \not\subset \mathcal{O}$. In particular, $\alpha_\Gamma^* \otimes \alpha_M^*(\mathbb{C}[\Gamma] \otimes_{\mathbb{C}} \mathbb{C}[X_\sigma]) \not\subset \mathcal{O}$, and $\alpha \in \mathcal{X}_{\text{ver}}$.

Now, we assume that α_Γ^* is not injective, so its kernel is the ideal of a \mathbb{C} -point, so $\ell_\alpha = 0$ and $\nu_\alpha \in \sigma$. This implies that $\alpha_\Gamma^* \otimes \alpha_M^*(\mathbb{C}[\Gamma] \otimes_{\mathbb{C}} \mathbb{C}[X_\sigma]) \subset \mathcal{O}$, which means that $\alpha \in \mathcal{X}_{\text{hor}}$. \square

Let us now study the $T(\mathcal{O})$ -action on the space X_Γ . Consider

$$\underline{\text{val}}: X_\Gamma \rightarrow C(\mathfrak{D}) \cap \mathcal{N},$$

which with an arc α associates the point $(y_\alpha, \nu_\alpha, \ell_\alpha)$ from Lemma 4.4. Our goal is to decompose into $T(\mathcal{O})$ -orbits the fibers of $\underline{\text{val}}$ above points of \mathcal{X}_{hor} and \mathcal{X}_{ver} . In the case of \mathcal{X}_{hor} , the result is immediate from [Ish04, Theorem 4.1].

LEMMA 4.7. *We have a decomposition*

$$\mathcal{X}_{\text{hor}} = \Gamma(\mathcal{O}) \times (X_\sigma(\mathcal{O}) \cap T(\mathcal{K})) = \Gamma(\mathcal{O}) \times \bigsqcup_{\nu \in \sigma \cap N} \mathcal{C}_\nu,$$

where $\alpha \in \mathcal{X}_{\text{hor}}$ is identified with the pair $(\alpha_\Gamma^*, \alpha_M^*) \in \Gamma(\mathcal{O}) \times (X_\sigma(\mathcal{O}) \cap T(\mathcal{K}))$ and

$$\mathcal{C}_\nu := \{\alpha_M^* \mid \alpha \in \mathcal{X}_{\text{hor}}, \nu_\alpha = \nu\}$$

is a $T(\mathcal{O})$ -orbit of $X_\sigma(\mathcal{O}) \cap T(\mathcal{K})$. Moreover,

$$\underline{\text{val}}(\mathcal{X}_{\text{hor}}) = \{(C, \nu, 0) \mid \nu \in \sigma \cap N\}$$

and $\underline{\text{val}}^{-1}(C, \nu, 0) = \Gamma(\mathcal{O}) \times \mathcal{C}_\nu$ for any $\nu \in \sigma \cap N$.

We now state a similar result for the subset \mathcal{X}_{ver} .

LEMMA 4.8. *Let α be an arc in \mathcal{X}_{ver} and $\pi \in \mathbb{C}(C)^*$ be a uniformizer of y_α . There exists a one-to-one correspondence between*

$$\mathcal{X}_{\text{ver}, \alpha} := \underline{\text{val}}^{-1}(\underline{\text{val}}(\alpha)) = \{\beta \in \mathcal{X}_{\text{ver}} \mid y_\beta = y_\alpha, \nu_\beta = \nu_\alpha, \ell_\beta = \ell_\alpha\}$$

and the set of pairs (ω, u) , where $\omega: M \rightarrow \mathcal{O}^*$ is a group homomorphism and $u \in \mathcal{O}^*$. The correspondence is given by $\beta \mapsto (\omega_\beta, R_\beta(\pi))$, where R_β is the function from Remark 4.3. It identifies the fiber $\mathcal{X}_{\text{ver}, \alpha}$ with the product $\mathcal{C}_{\nu_\alpha} \times \mathcal{O}^*$. Furthermore, we have

$$\underline{\text{val}}(\mathcal{X}_{\text{ver}}) = \{(y, \nu, \ell) \in C(\mathfrak{D}) \cap \mathcal{N} \mid y \in C_0 \setminus \Gamma \text{ and } \ell \geq 1\}. \quad (4.1)$$

Proof. We first prove the surjectivity of the correspondence. Fix a pair $(\omega, u) \in T(\mathcal{O}) \times \mathcal{O}^*$ and write $y = y_\alpha$, $\nu = \nu_\alpha$, and $\ell = \ell_\alpha$. From [Eis95, Theorem 7.16], we know that there exists a unique morphism $\phi: \hat{\mathcal{O}}_y = \mathbb{C}[[\pi]] \rightarrow \mathcal{O}$ such that $\phi(\pi) = t^\ell u$, where $\hat{\mathcal{O}}_y$ is the formal completion of $(\mathcal{O}_y, \pi \mathcal{O}_y)$. When we restrict to $\mathbb{C}[C_0]$, since $\ell \neq 0$, the morphism ϕ induces an injective homomorphism $\mathbb{C}[C_0] \rightarrow \mathcal{O}$; see Lemma 4.6. Extending it to the fraction field, we obtain a homomorphism $\mathbb{C}(C_0) \rightarrow \mathcal{K}$, whose restriction to $\mathbb{C}[\Gamma]$ is denoted by λ . We define an arc $\beta \in \mathcal{X}_{\text{ver}}$ by setting $\bar{\beta}^*(f \otimes \chi^m) = \lambda(f) t^{\langle m, \nu \rangle} \omega(m)$ for any homogeneous element $f \otimes \chi^m \in \mathbb{C}[\Gamma] \otimes_{\mathbb{C}} \mathbb{C}[\sigma^\vee \cap M]$. The arc β is in \mathcal{X}_{ver} since $\ell_\beta = \ell \neq 0$ and $y_\beta = y \in C_0 \setminus \Gamma$.

To prove that the correspondence is injective, it is enough to check that for $\beta \in \mathcal{X}_{\text{ver}}$, the map $\lambda: \mathbb{C}[\Gamma] \rightarrow \mathcal{K}$ above is uniquely determined by $\ell = \ell_\beta$, $y = y_\beta$, and $R_\beta(\pi)$, where $\pi \in \mathbb{C}(C)^*$ is a uniformizer of y . Clearly, λ induces a continuous morphism $\bar{\lambda}: (\mathcal{O}_y, \pi\mathcal{O}_y) \rightarrow (\mathcal{O}, t\mathcal{O})$, that is, a morphism such that $\bar{\lambda}(\pi\mathcal{O}_y) \subset t\mathcal{O}$. Taking formal completions, we also get a morphism $\tilde{\lambda}: \hat{\mathcal{O}}_y = \mathbb{C}[[\pi]] \rightarrow \mathcal{O}$; see [Mat80, Section 23.H]. Using [Eis95, Theorem 7.16] again, we see that $\tilde{\lambda}$ is the unique morphism sending π to $t^\ell R_\beta(\pi)$. We conclude by noticing that λ is uniquely determined by $\tilde{\lambda}$, which proves the injectivity.

To conclude the proof, we check equation (4.1). The direct inclusion of $\underline{\text{val}}(\mathcal{X}_{\text{ver}})$ has been proved by combining Lemmas 4.4 and 4.6. For the other inclusion, consider a triple $(y, \nu, \ell) \in C(\mathfrak{D}) \cap \mathcal{N}$ with $y \in C_0 \setminus \Gamma$ and $\ell \neq 0$. Choose a uniformizer π of y , and consider the unique morphism $\hat{\mathcal{O}}_y = \mathbb{C}[[\pi]] \rightarrow \mathcal{O}$ which sends π to t^ℓ . By the same argument as before, it implies the existence of a morphism $\bar{\beta}^*: A(C_0, \mathfrak{D}) \rightarrow \mathcal{O}$ such that $\bar{\beta}^*(f \otimes \chi^m) := t^{\ell \text{ord}_y(f) + \langle m, \nu \rangle}$, hence the existence of an arc $\beta \in \mathcal{X}_{\text{ver}}$ such that $\underline{\text{val}}(\beta) = (y, \nu, \ell)$. \square

4.2 The arc space of a normal T -variety of complexity one

In this section, we generalize the results of Section 4.1 to the non-affine case. We still assume that $G = T$ is a torus and $H = \{e\}$ is trivial.

We want to describe the arc space of $X = X(\mathcal{E})$ in terms of the arc spaces of the affine charts $X(\mathfrak{D})$ for polyhedral divisors $\mathfrak{D} \in \mathcal{E}$, which may have non-affine loci. So to apply the previous results, we need to replace X with a T -variety \tilde{X} associated with a divisorial fan $\tilde{\mathcal{E}}$ such that all the polyhedral divisors in $\tilde{\mathcal{E}}$ are defined on open dense *affine* subsets of C . We call this process *affinization*.

Notation 4.9. Keeping the same notation as in Section 4.1, for any $\mathfrak{D}^i \in \mathcal{E}$, we consider a finite, open, dense, affine covering $(C_j^i)_{j \in J_i}$ of the curve C^i . Denote by \mathfrak{D}_j^i the polyhedral divisor obtained as the restriction of \mathfrak{D}^i to the open affine subset C_j^i and by $\tilde{\mathcal{E}}$ the divisorial fan constituted of all the \mathfrak{D}_j^i . Then the T -variety $\tilde{X} = X(\tilde{\mathcal{E}})$ does not depend on the choices of the affine coverings, and its support $|\tilde{\mathcal{E}}|$ coincides with that of \mathcal{E} .

From [AH06, Theorem 3.1], it follows that the inclusions $A(C^i, \mathfrak{D}^i) \hookrightarrow A(C_j^i, \mathfrak{D}_j^i)$ induce a proper T -equivariant birational morphism

$$q: X(\tilde{\mathcal{E}}) \rightarrow X(\mathcal{E}). \quad (4.2)$$

As in Section 4.1, we introduce a morphism $\underline{\text{val}}$ defined on X_Γ , whose image will be contained in

$$|\mathcal{E}|_\Gamma := \bigcup_{\mathfrak{D} \in \mathcal{E}} C_\Gamma(\mathfrak{D}) \subset \mathcal{N}_\mathbb{Q}, \quad (4.3)$$

where $C_\Gamma(\mathfrak{D}) = C(\mathfrak{D}) \setminus \{(y, \nu, \ell) \mid y \in \Gamma, \nu \in N_\mathbb{Q}, \ell > 0\}$. Clearly, $|\mathcal{E}|_\Gamma = |\tilde{\mathcal{E}}|_\Gamma$.

The following result extends Lemmas 4.7 and 4.8 to the T -variety X .

PROPOSITION 4.10. *Let \mathcal{E} be a divisorial fan on (C, T) , and write $X = X(\mathcal{E})$. Consider a dense open subset $\Gamma \subset C$ which does not contain any special point. There exists a surjective map*

$$\underline{\text{val}}: X_\Gamma \rightarrow |\mathcal{E}|_\Gamma \cap \mathcal{N}, \quad \alpha \mapsto (y_\alpha, \nu_\alpha, \ell_\alpha), \quad (4.4)$$

where $|\mathcal{E}|_\Gamma$ is as in equation (4.3) and \mathcal{N} as in Definition 3.8. Moreover,

$$\underline{\text{val}}^{-1}(y_\alpha, \nu_\alpha, \ell_\alpha) = \begin{cases} \Gamma(\mathcal{O}) \times C_{\nu_\alpha} & \text{if } \ell_\alpha = 0, \\ \mathcal{O}^* \times C_{\nu_\alpha} & \text{if } \ell_\alpha \geq 1. \end{cases}$$

Proof. Recall the morphism $q: \tilde{X} \rightarrow X$ from equation (4.2). We first check that X_Γ identifies with

$$\tilde{X}_\Gamma := \{\alpha \in \tilde{X}(\mathcal{O}) \mid \alpha(\eta) \in \Gamma \times T\}.$$

Indeed, we know that $q|_{\Gamma \times T}$ is the identity map. Write $X_1 := X \setminus (\Gamma \times T)$. By the valuative criterion of properness, the morphism q induces a bijection

$$\mathcal{L}(\tilde{X}) \setminus \mathcal{L}(q^{-1}(X_1)) \xrightarrow{\sim} \mathcal{L}(X) \setminus \mathcal{L}(X_1).$$

This implies that $X_\Gamma \cong \tilde{X}_\Gamma$, so we will assume $\mathcal{E} = \tilde{\mathcal{E}}$ in the rest of the proof.

We now prove that $\underline{\text{val}}$ is well defined and surjective. Clearly, the arc space has a covering

$$X_\Gamma = \bigcup_{\mathfrak{D} \in \mathcal{E}} X(\mathfrak{D})_\Gamma,$$

where $X(\mathfrak{D})_\Gamma := \{\alpha \in X_\Gamma \mid \alpha(0) \in X(\mathfrak{D})\}$. Fixing a uniformizer for each point of $C \setminus \Gamma$ and combining Lemmas 4.7 and 4.8, we get well-defined surjective maps

$$\underline{\text{val}}_{\mathfrak{D}}: X(\mathfrak{D})_\Gamma \rightarrow C_\Gamma(\mathfrak{D}) \cap \mathcal{N},$$

which are clearly compatible and glue into $\underline{\text{val}}$. Finally, the description of the fibers of $\underline{\text{val}}$ is a consequence of Lemma 4.7 when $\ell_\alpha = 0$ and of Lemma 4.8 when $\ell_\alpha \geq 1$. \square

4.3 The general case

Let us now treat the case of a horospherical G -variety X of complexity one. We start by recalling the complexity zero case.

Let G/H be a horospherical homogeneous space and P, I, T, M , and N be as in Notation 4.1. A horospherical embedding Y of G/H is parametrized by a colored fan Σ on $N_{\mathbb{Q}}$; see [Kno91, Theorem 3.3]. Let $|\Sigma|$ be the support of Σ , that is, the union $|\Sigma| := \bigcup_{(\sigma, \mathcal{F}) \in \Sigma} \sigma$, where σ is a strongly convex cone and $\mathcal{F} \subset \mathcal{F}_{G/H}$ is a subset of colors. The following theorem describes the arc space of Y in terms of $|\Sigma|$.

THEOREM 4.11 ([BM13, Theorem 3.1]). *Let Y be a horospherical G/H -embedding defined by a colored fan Σ . Then there exists a surjective map*

$$\mathcal{V}: Y(\mathcal{O}) \cap (G/H)(\mathcal{K}) \rightarrow |\Sigma| \cap N,$$

whose fiber over $\nu \in |\Sigma| \cap N$ is a $G(\mathcal{O})$ -orbit Ω_ν . In particular, we obtain a one-to-one correspondence between the lattice points in $|\Sigma| \cap N$ and the $G(\mathcal{O})$ -orbits in $Y(\mathcal{O}) \cap (G/H)(\mathcal{K})$.

Let us sketch the construction of the map \mathcal{V} . After discoloring, using the valuative criterion of properness, we may assume $Y = G \times^P Y_\Sigma$, where Y_Σ is the T -variety with fan Σ . Since $T = P/H \subset G/H$, the closure $Y_\Sigma = \bar{T}$ embeds into Y . We have a commutative diagram:

$$\begin{array}{ccc} Y_\Sigma(\mathcal{O}) \cap T(\mathcal{K}) & \xrightarrow{\Psi} & |\Sigma| \cap N \\ \downarrow & \nearrow \mathcal{V} & \\ Y(\mathcal{O}) \cap (G/H)(\mathcal{K}), & & \end{array} \quad (4.5)$$

where the map Ψ comes from [Ish04, Corollary 4.3]. Denote by \mathcal{C}_ν the fiber of Ψ over $\nu \in |\Sigma| \cap N$. The map \mathcal{V} extends Ψ in such a way that Ω_ν is the unique $G(\mathcal{O})$ -orbit containing \mathcal{C}_ν .

For the following theorem, which deals with the complexity one case, we use the setting of Notation 4.1.

THEOREM 4.12. *Let $X := X(\mathcal{E})$, where \mathcal{E} is a colored divisorial fan on $(C, G/H)$. Let Γ be a dense, open, affine subset of C which does not contain any special point. There exists a surjective map*

$$\underline{\text{val}}: X_\Gamma = X(\mathcal{O}) \cap (\Gamma \times G/H)(\mathcal{K}) \rightarrow |\mathcal{E}|_\Gamma \cap \mathcal{N}, \quad \alpha \mapsto (y_\alpha, \nu_\alpha, \ell_\alpha),$$

where

$$|\mathcal{E}|_\Gamma := \bigcup_{(\mathfrak{D}, \mathcal{F}) \in \mathcal{E}} C_\Gamma(\mathfrak{D}) \subset \mathcal{N}_\mathbb{Q}$$

and \mathcal{N} and $\mathcal{N}_\mathbb{Q}$ are as in Definition 3.8. Moreover, it satisfies

$$\underline{\text{val}}^{-1}(y_\alpha, \nu_\alpha, \ell_\alpha) = \begin{cases} \Gamma(\mathcal{O}) \times \Omega_{\nu_\alpha} & \text{if } \ell_\alpha = 0, \\ \mathcal{O}^* \times \Omega_{\nu_\alpha} & \text{if } \ell_\alpha \geq 1, \end{cases}$$

where the Ω_{ν_α} are as in Theorem 4.11.

Proof. First, we discolor X using the map $\pi_{\text{dis}}: X_{\text{dis}} \rightarrow X$ from equation (3.5). We have $X_{\text{dis}} = G \times^P V(\mathcal{E})$, where $V(\mathcal{E})$ is as in equation (3.6). Then, we replace the colored divisorial fan \mathcal{E} with another fan $\tilde{\mathcal{E}}$ using the affinization map q from equation (4.2), obtaining a proper birational morphism $\Theta: G \times^P V(\tilde{\mathcal{E}}) \rightarrow X$ which restricts to the identity on $\Gamma \times G/H$. By the valuative criterion of properness, it is equivalent to consider arcs on X or on $G \times^P V(\tilde{\mathcal{E}})$, so from now on we assume $X = G \times^P V(\tilde{\mathcal{E}})$.

Next, we compare X_Γ , the set of K -valued formal arcs on X with generic point in $\Gamma \times T$, with

$$V(\tilde{\mathcal{E}})_\Gamma = \{\alpha: \text{Spec } \mathcal{O} \rightarrow V(\tilde{\mathcal{E}}) \mid \alpha(\eta) \in \Gamma \times T\} \subset \mathcal{L}(V(\tilde{\mathcal{E}}))(K).$$

By the construction of $X = G \times^P V(\tilde{\mathcal{E}})$, the closure of $\Gamma \times T$ embeds in X and identifies with $V(\tilde{\mathcal{E}})$. The variety $V(\tilde{\mathcal{E}})$ will play the same role as Y_Σ in equation (4.5). We have a map $\Psi: V(\tilde{\mathcal{E}})_\Gamma \rightarrow |\tilde{\mathcal{E}}|_\Gamma \cap \mathcal{N}$, which is the map $\underline{\text{val}}$ from Proposition 4.10.

From the proof of [BM13, Theorem 3.1], we obtain a map $\mathcal{V}: (G/H)(\mathcal{K}) \rightarrow N$ which is constant on the $G(\mathcal{O})$ -orbits and whose restriction to $T(\mathcal{K}) \subset (G/H)(\mathcal{K})$ is constructed from the standard valuation map $\text{ord}: \mathcal{K}^* \rightarrow \mathbb{Z}$ as in [BM13, Lemma 3.2]. We use it to build part of a map from $(\Gamma \times G/H)(\mathcal{K})$ to \mathcal{N} , which we will then restrict to X_Γ .

To get the other part of the map, as in Remark 4.3, we parametrize $\alpha \in \Gamma(\mathcal{K})$ by the pair (y_α, ℓ_α) , where $\alpha^*(f) = t^{\ell_\alpha \text{ord}_{y_\alpha}(f)} R_\alpha(f)$ for any $f \in \mathbb{C}[\Gamma]$. Finally,

$$\underline{\text{val}}: (\Gamma \times G/H)(\mathcal{K}) \rightarrow \mathcal{N}, \quad (\alpha, \beta) \mapsto (y_\alpha, \nu_\beta, \ell_\alpha),$$

where $\nu_\beta = \mathcal{V}(\beta)$. Restricted to $V(\tilde{\mathcal{E}})_\Gamma$, this map is simply Ψ , and it is constant on the $G(\mathcal{O})$ -orbits.

We now study the restriction of $\underline{\text{val}}$ to X_Γ , which we denote again in the same way. Consider the quotient map $\varphi: X \rightarrow G/P$ and the corresponding map $X(\mathcal{O}) \rightarrow (G/P)(\mathcal{O})$ on the set of \mathcal{O} -valued points. We denote by $\varphi_\infty: X_\Gamma \rightarrow (G/P)(\mathcal{O})$ its restriction to X_Γ . It extends to the natural map

$$\bar{\varphi}_\infty: \Gamma(\mathcal{K}) \times (G/H)(\mathcal{K}) \rightarrow (G/P)(\mathcal{K}).$$

Since $(G/P)(\mathcal{K}) = (G/P)(\mathcal{O})$ by the valuative criterion of properness, the image of $\bar{\varphi}_\infty$ is in fact contained in $(G/P)(\mathcal{O})$, which is equal to $G(\mathcal{O})/P(\mathcal{O})$ by the local triviality of the quotient map

$G \rightarrow G/P$. Moreover, the map φ_∞ is $G(\mathcal{O})$ -equivariant. If $\alpha \in X_\Gamma$, then by transitivity and $G(\mathcal{O})$ -equivariance, there exists a $g \in G(\mathcal{O})$ such that $\varphi_\infty(g \cdot \alpha) = p_0$, where $p_0 = P(\mathcal{O}) \in (G/P)(\mathcal{O})$. Hence

$$g \cdot \alpha \in \varphi_\infty^{-1}(p_0) \subset \bar{\varphi}_\infty^{-1}(p_0) = (\Gamma \times T)(\mathcal{K}).$$

It follows that $\overline{g \cdot \alpha} \in (\Gamma \times T)(\mathcal{K}) \cap X_\Gamma$ and $(\Gamma \times T)(\mathcal{K}) \cap X_\Gamma \subset V(\tilde{\mathcal{E}})_\Gamma$. Indeed, if $\beta \in (\Gamma \times T)(\mathcal{K}) \cap X_\Gamma$, then $\beta(0) \in \bar{\beta}(\eta) \subset \bar{\Gamma} \times \bar{T} = V(\tilde{\mathcal{E}})$; thus, β is an element of $V(\tilde{\mathcal{E}})_\Gamma$. As a result, $g \cdot \alpha \in V(\tilde{\mathcal{E}})_\Gamma$, and $\underline{\text{val}}(\alpha) = \underline{\text{val}}(g \cdot \alpha) = \Psi(g \cdot \alpha)$. This implies that $\underline{\text{val}}(X_\Gamma) = \Psi(V(\tilde{\mathcal{E}})_\Gamma) = |\tilde{\mathcal{E}}|_\Gamma \cap \mathcal{N}$.

To conclude, we compute the fibers of the restriction $\underline{\text{val}}: X_\Gamma \rightarrow |\tilde{\mathcal{E}}|_\Gamma \cap \mathcal{N}$. Consider $(y, \nu, \ell) \in |\tilde{\mathcal{E}}|_\Gamma \cap \mathcal{N}$. For any $\alpha \in \underline{\text{val}}^{-1}(y, \nu, \ell)$, by a previous argument, there exists a $g \in G(\mathcal{O})$ such that $g \cdot \alpha \in V(\tilde{\mathcal{E}})_\Gamma \cap \underline{\text{val}}^{-1}(y, \nu, \ell)$. Finally, by Proposition 4.10, we know that

$$V(\tilde{\mathcal{E}})_\Gamma \cap \underline{\text{val}}^{-1}(y, \nu, \ell) = \begin{cases} \Gamma(\mathcal{O}) \times \mathcal{C}_\nu & \text{if } \ell = 0, \\ \mathcal{O}^* \times \mathcal{C}_\nu & \text{if } \ell \geq 1. \end{cases} \quad \square$$

4.4 Motivic volumes

Assuming that X is smooth, we now compute the motivic measure of the fibers of the map $\underline{\text{val}}$ from Theorem 4.12.

We start by studying truncations of arcs in X_Γ . Using the discoloration morphism, we may assume that \mathcal{E} has trivial coloration, so that $X = G \times^P V(\mathcal{E})$. Recall that there is a surjective quotient map $\varphi: X \rightarrow G/P$. The next result, obtained from Theorem 4.12, gives a comparison between the jet spaces of X and those of the flag variety G/P .

LEMMA 4.13. *Consider $\xi := (y, \nu, \ell) \in |\mathcal{E}|_\Gamma \cap \mathcal{N}$ and $q \in \mathbb{N}$, where $|\mathcal{E}|_\Gamma$ is as in equation (4.3). Then the restriction to $\pi_q(\underline{\text{val}}^{-1}(\xi))$ of the bundle of q -jets $\varphi_q: \mathcal{L}_q(X) \rightarrow \mathcal{L}_q(G/P)$ is a bundle with fiber isomorphic to $\pi'_q(V(\mathcal{E})_\Gamma \cap \underline{\text{val}}^{-1}(\xi))$, where $\pi'_q: \mathcal{L}(V(\mathcal{E})) \rightarrow \mathcal{L}_q(V(\mathcal{E}))$ is the truncation map.*

Proof. We have a commutative diagram

$$\begin{array}{ccc} \underline{\text{val}}^{-1}(\xi) & \longrightarrow & \mathcal{L}(G/P) \\ \downarrow & & \downarrow \\ \pi_q(\underline{\text{val}}^{-1}(\xi)) & \longrightarrow & \mathcal{L}_q(G/P), \end{array}$$

where the vertical maps are arc truncations and the horizontal maps are induced by $\varphi: X \rightarrow G/P$. The vertical map on the left-hand side is clearly surjective, and the other also is since G/P is smooth (see [Gre66]). Finally, the top horizontal map is surjective by the proof of Theorem 4.12; hence, so is the bottom map. The last claim in the lemma follows from the description of the fibers of the top map. \square

Using Lemma 4.13, we now show that the fibers of $\underline{\text{val}}$ are cylinders, hence measurable. Lemma 4.14 deals with the horizontal fibers, while Lemma 4.15 takes care of the vertical fibers.

LEMMA 4.14. *Let X be as in Notation 4.1. Assume that X is smooth of dimension d and that \mathcal{E} has trivial coloration. Consider $\xi := (y, \nu, 0) \in |\mathcal{E}|_\Gamma \cap \mathcal{N}$. Let n be the rank of the lattice N and $\sigma \in \Sigma(\mathcal{E})$ be a cone containing ν , and put $r := \dim \sigma$. The linear part $\sigma^\vee \cap (-\sigma^\vee)$ of σ^\vee is*

a $(d - 1 - r)$ -dimensional vector space $V_{\mathbb{Q}}$. Let $W_{\mathbb{Q}}$ be a complement of $V_{\mathbb{Q}}$ in $M_{\mathbb{Q}}$ and u_1, \dots, u_r be an integral basis of $\sigma^{\vee} \cap W_{\mathbb{Q}}$.

Then for any $q \geq \max(\{\langle u_j, \nu \rangle \mid 1 \leq j \leq r\})$, the set $\underline{\text{val}}^{-1}(\xi) \cap V(\mathcal{E})_{\Gamma}$ is a cylinder with q -basis

$$\mathcal{L}_q(\Gamma) \times (\mathbb{A}^1 \setminus 0)^n \times \mathbb{A}^{qm - \sum_{j=1}^r \langle u_j, \nu \rangle}.$$

Proof. By the smoothness criterion of [KKMS73, Chapter II], any cone $\sigma \in \Sigma(\mathcal{E})$ is generated by part of a basis of N . Consider $\alpha \in \underline{\text{val}}^{-1}(\xi) \cap V(\mathcal{E})_{\Gamma}$ and the morphisms $\alpha_{\Gamma}^*: \mathbb{C}[\Gamma] \rightarrow \mathcal{O}$ and $\alpha_M^*: \mathbb{C}[\sigma^{\vee} \cap M] \rightarrow \mathcal{O}$ from Remark 4.3. The maps α_{Γ}^* and α_M^* induce arcs on Γ and X_{σ} , which can be truncated to q -jets $\alpha'_{\Gamma} \in \mathcal{L}_q(\Gamma)$ and $\alpha'_M \in \mathcal{L}_q(X_{\sigma})$. Moreover, the set $\{\alpha'_{\Gamma} \mid \alpha \in \underline{\text{val}}^{-1}(\xi) \cap V(\mathcal{E})_{\Gamma}\}$ is isomorphic to $\mathcal{L}_q(\Gamma)(K)$ since Γ is smooth. To conclude, we use an adapted version of [BM13, Lemma 3.4], where we do not assume the cone to be full-dimensional. The result of the lemma implies that

$$\{\alpha'_M \mid \alpha \in \underline{\text{val}}^{-1}(\xi) \cap V(\mathcal{E})_{\Gamma}\} \simeq (\mathbb{A}^1(K) \setminus 0)^n \times \mathbb{A}^{qm - \sum_{j=1}^r \langle u_j, \nu \rangle}(K). \quad \square$$

LEMMA 4.15. *Let X be as in Notation 4.1. Assume that X is smooth of dimension d and that \mathcal{E} has trivial coloration, and denote by n the rank of the lattice N . Consider $\xi := (y, \nu, \ell) \in |\mathcal{E}|_{\Gamma} \cap \mathcal{N}$ such that $\ell \geq 1$. Let $(\mathfrak{D}, \mathcal{F}) \in \mathcal{E}$ be such that $\xi \in C_{\Gamma}(\mathfrak{D})$, and let σ be the tail of \mathfrak{D} . Denote by r the dimension of σ and by $s \geq r + 1$ that of the Cayley cone $C_y(\mathfrak{D})$. The linear part $C_y(\mathfrak{D})^{\vee} \cap (-C_y(\mathfrak{D}))^{\vee}$ of $C_y(\mathfrak{D})^{\vee}$ is a $(d - s)$ -dimensional vector space $V_{\mathbb{Q}}$. Let $W_{\mathbb{Q}}$ be a complement of $V_{\mathbb{Q}}$ in $\Lambda_{\mathbb{Q}} = M_{\mathbb{Q}} \oplus \mathbb{Q}$, and denote by $\{(u_1, 0), \dots, (u_r, 0), w_1, \dots, w_{s-r}\}$ an integral basis of $C_y(\mathfrak{D})^{\vee} \cap W_{\mathbb{Q}}$, where the u_i are in $\sigma^{\vee} \cap M$.*

Then for any q greater than $\max(\{\langle u_j, \nu \rangle \mid 1 \leq j \leq r\} \cup \{\langle w_j, (\nu, \ell) \rangle \mid 1 \leq j \leq s - r\})$, the set $\underline{\text{val}}^{-1}(\xi) \cap V(\mathcal{E})_{\Gamma}$ is a cylinder with q -basis

$$(\mathbb{A}^1 \setminus 0)^{n+1} \times \mathbb{A}^{q(n+1) - (\sum_{j=1}^r \langle u_j, \nu \rangle + \sum_{j=1}^{s-r} \langle w_j, (\nu, \ell) \rangle)}.$$

Proof. Let $\pi \in \mathbb{C}(C)^*$ be a uniformizer of y . Writing $\Lambda = M \oplus \mathbb{Z}$, we have

$$\mathbb{C}[C_y(\mathfrak{D})^{\vee} \cap \Lambda] = \{\pi^k \otimes \chi^m \mid (m, k) \in C_y(\mathfrak{D})^{\vee} \cap \Lambda\}.$$

Denote the associated toric variety by $X_{C_y(\mathfrak{D})} := \text{Spec } \mathbb{C}[C_y(\mathfrak{D})^{\vee} \cap \Lambda]$. The restricted fiber $\underline{\text{val}}^{-1}(\xi) \cap V(\mathcal{E})_{\Gamma}$ identifies with the $(T \times \mathbb{G}_m)(\mathcal{O})$ -orbit $C_{\nu, \ell}$ of $X_{C_y(\mathfrak{D})}(\mathcal{O}) \cap (T \times \mathbb{G}_m)(\mathcal{K})$ given in [Ish04, Theorem 4.1].

Indeed, as in the proof of Lemma 4.8, any arc α in the restricted fiber induces a morphism $\mathbb{C}[[\pi]] \otimes_{\mathbb{C}} \mathbb{C}[M] \rightarrow \mathcal{K}$, which restricts to $\mathbb{C}[C_y(\mathfrak{D})^{\vee} \cap \Lambda] \rightarrow \mathcal{O}$. Conversely, if we have an arc $\beta \in \mathcal{L}(X_{C_y(\mathfrak{D})})(K)$ with the property above, it induces a morphism $\mathbb{C}[\pi, \pi^{-1}] \otimes_{\mathbb{C}} \mathbb{C}[M] \rightarrow \mathcal{K}$. Since the completion of $(\mathbb{C}[\pi, \pi^{-1}], \pi \mathbb{C}[\pi, \pi^{-1}])$ is $\mathbb{C}((\pi))$, by [Eis95, Theorem 7.16], the arc β gives a morphism $\mathbb{C}[[\pi]] \otimes_{\mathbb{C}} \mathbb{C}[M] \rightarrow \mathcal{K}$ which restricts to a co-morphism of an arc in $\underline{\text{val}}^{-1}(\xi) \cap V(\mathcal{E})_{\Gamma}$. The rest of the proof follows from the suitably modified version of [BM13, Lemma 3.4] already used in Lemma 4.14. \square

The next result gives the motivic volume of the fibers of the surjective map $\underline{\text{val}}: X_{\Gamma} \rightarrow |\mathcal{E}|_{\Gamma} \cap \mathcal{N}$. Thus we obtain, up to a subset of motivic measure zero, a decomposition of the arc space of X as a disjoint union of measurable subsets of known motivic volume, which concludes our study of $\mathcal{L}(X)$.

THEOREM 4.16. *Let \mathcal{E} be a colored divisorial fan on $(C, G/H)$ such that $X = X(\mathcal{E})$ is smooth of dimension d . Without loss of generality, we may assume that \mathcal{E} has trivial coloration.*

Consider $\xi := (y, \nu, \ell) \in |\mathcal{E}|_\Gamma \cap \mathcal{N}$, where $|\mathcal{E}|_\Gamma := \bigcup_{(\mathfrak{D}, \mathcal{F}) \in \mathcal{E}} C_\Gamma(\mathfrak{D}) \subset \mathcal{N}_\mathbb{Q}$ and \mathcal{N} and $\mathcal{N}_\mathbb{Q}$ are as in Definition 3.8. Let $(\mathfrak{D}, \mathcal{F}) \in \mathcal{E}$ be such that $\xi \in C_\Gamma(\mathfrak{D})$, and let σ be the tail of \mathfrak{D} . Denote by r the dimension of σ and by $s \geq r + 1$ that of the Cayley cone $C_y(\mathfrak{D})$. The linear part $C_y(\mathfrak{D})^\vee \cap (-C_y(\mathfrak{D})^\vee)$ of $C_y(\mathfrak{D})^\vee$ is a $(d - s)$ -dimensional vector space $V_\mathbb{Q}$. Let $W_\mathbb{Q}$ be a complement of $V_\mathbb{Q}$ in $\Lambda_\mathbb{Q} = M_\mathbb{Q} \oplus \mathbb{Q}$, and denote by $\{(u_1, 0), \dots, (u_r, 0), w_1, \dots, w_{s-r}\}$ an integral basis of $C_y(\mathfrak{D})^\vee \cap W_\mathbb{Q}$, where the u_i are in $\sigma^\vee \cap M$. Then

$$\mu_X(\underline{\text{val}}^{-1}(\xi)) = \begin{cases} [\Gamma][G/H] \mathbb{L}^{-\sum_{j=1}^r \langle u_j, \nu \rangle} & \text{if } \ell = 0, \\ [G/H](\mathbb{L} - 1) \mathbb{L}^{-\sum_{j=1}^s \langle u_j, \nu \rangle - \sum_{j=1}^{s-r} \langle w_j, (\nu, \ell) \rangle} & \text{if } \ell \geq 1. \end{cases}$$

Proof. For $\ell = 0$, since G/P is smooth, it follows by Lemmas 4.13 and 4.14 that for large enough $q \geq 0$,

$$\begin{aligned} \mu_X(\underline{\text{val}}^{-1}(C, \nu, 0)) &= [\pi'_q(V(\mathcal{E})_\Gamma \cap \underline{\text{val}}^{-1}(\xi))] [\mathcal{L}_q(G/P)] \mathbb{L}^{-qd} \\ &= [\mathcal{L}_q(\Gamma)] (\mathbb{L} - 1)^n [G/P] \mathbb{L}^{q(n + \dim(G/P) - d) - \sum_{j=1}^r \langle u_j, \nu \rangle}. \end{aligned}$$

The result for $\ell = 0$ follows from the equalities $\dim(G/P) = d - 1 - n$, $[G/H] = (\mathbb{L} - 1)^n [G/P]$, and $\mathcal{L}_q(\Gamma) = [\Gamma] \mathbb{L}^q$. For the case $\ell \geq 1$, we have by Lemmas 4.13 and 4.15 the equality

$$\mu_X(\underline{\text{val}}^{-1}(\xi)) = (\mathbb{L} - 1)^{n+1} [G/P] \mathbb{L}^{q(n+1 + \dim(G/P) - d) - \sum_{j=1}^s \langle u_j, \nu \rangle - \sum_{j=1}^{s-r} \langle w_j, (\nu, \ell) \rangle},$$

which simplifies to our desired formula. \square

5. Computing the stringy E -function

Let $X = X(\mathcal{E})$ be a log terminal, horospherical variety of complexity one. In Theorem 5.16, we compute the stringy motivic volume of X . As in the complexity zero case, see [BM13], Theorem 5.16 requires X to be \mathbb{Q} -Gorenstein and log terminal; we introduce the related notions in Section 5.2. In Section 5.3, we construct a desingularization of X in terms of its colored divisorial fan, and in Section 5.4, we put the previous results to use by computing the discrepancy. This enables us to prove Theorem 5.16 in Section 5.5. Throughout this section, we follow the conventions of Notation 4.1.

5.1 Canonical class

The canonical class K_X of X can be expressed as a linear combination of B -invariant divisors; see [LT16, Sections 2.3 and 2.4]. By the description in [Tim11, Section 16], there are two types of G -divisors called *vertical* and *horizontal*, depending on whether the G -action has complexity zero or one. The set of *vertical* G -divisors on X is parametrized by

$$\text{Vert}(\mathcal{E}) := \bigcup_{i \in J} \text{Vert}(\mathfrak{D}^i),$$

where for any i in J , we denote by $\text{Vert}(\mathfrak{D}^i)$ (equal to $\text{Vert}(\mathfrak{D}^i, \mathcal{F}^i)$) the set of pairs (y, p) such that y is in C^i and p is a vertex of Δ_y^i . The rest of the G -invariant divisors of X are *horizontal* and parametrized by

$$\text{Ray}(\mathcal{E}) := \bigcup_{i \in J} \text{Ray}(\mathfrak{D}^i, \mathcal{F}^i),$$

where for any i in J , we denote by $\text{Ray}(\mathfrak{D}^i, \mathcal{F}^i)$ the set of rays ρ of σ_i such that $\rho \cap \varrho(\mathcal{F}^i)$ is empty (namely, the ray ρ is uncolored) and $\rho \cap \deg(\mathfrak{D}^i)$ is empty if C^i is projective. Here we used the same notation ρ for a ray and for the corresponding primitive generator.

THEOREM 5.1 ([LT16, Theorem 2.11]). *Let $\text{Div}(\mathcal{E})$ denote the set of G -divisors of X . There exists a bijection*

$$\text{Vert}(\mathcal{E}) \bigsqcup \text{Ray}(\mathcal{E}) \rightarrow \text{Div}(\mathcal{E}),$$

where we denote by $D_{(y,p)}$, respectively D_ρ , the G -divisor corresponding to the pair $(y,p) \in \text{Vert}(\mathcal{E})$, respectively to $\rho \in \text{Ray}(\mathcal{E})$.

We may now describe the canonical class of X as a Weil divisor.

THEOREM 5.2 ([LT16, Theorem 2.18]). *With the same notation as in Theorem 5.1, the divisor*

$$K_X = \sum_{(y,p) \in \text{Vert}(\mathcal{E})} (\kappa(p)b_y + \kappa(p) - 1) \cdot D_{(y,p)} - \sum_{\rho \in \text{Ray}(\mathcal{E})} D_\rho - \sum_{\alpha \in \Phi \setminus I} a_\alpha \cdot D_\alpha$$

is a canonical divisor of X . Here $K_C = \sum_{y \in C} b_y \cdot [y]$ is a canonical divisor on C , and $a_\alpha := \sum_{\beta \in R^+ \setminus R_I} \langle \beta, \alpha^\vee \rangle$, where R^+ is the set of positive roots of G and R_I is the set of roots of $P = N_G(H)$.

5.2 Cartier divisors and support functions

We recall the combinatorial description of invariant Cartier divisors on horospherical varieties of complexity one from [Tim11, Section 17] and [LT16, Corollary 2.17], via functions on hypercones called *support functions*. We refer to [PS11] for the setting of torus actions. Then, we give a criterion for these varieties to have \mathbb{Q} -Gorenstein or log terminal singularities.

Denote by $\mathbb{C}(X)^{(B)}$ the set of B -eigenfunctions in the function field $\mathbb{C}(X)$ of X , which identifies with a subset of the tensor product $\mathbb{C}(C) \otimes_{\mathbb{C}} \mathbb{C}[M]$. The principal divisor associated with a B -eigenfunction $f \otimes \chi^m$ in $\mathbb{C}(C) \otimes_{\mathbb{C}} \mathbb{C}[M]$ is given by

$$\begin{aligned} \text{div}(f \otimes \chi^m) &= \sum_{(y,p) \in \text{Vert}(\mathcal{E})} \kappa(p) (\langle m, p \rangle + \text{ord}_y(f)) \cdot D_{(y,p)} \\ &\quad + \sum_{\rho \in \text{Ray}(\mathcal{E})} \langle m, \rho \rangle \cdot D_\rho + \sum_{D \in \mathcal{F}_{G/H}} \langle m, \varrho(D) \rangle \cdot D, \end{aligned}$$

where $\kappa(p) = \min\{\lambda \in \mathbb{Z}_{>0} \mid \lambda \cdot p \in N\}$. Cartier divisors are locally principal divisors. Invariant Cartier divisors on X will be associated with some *support functions* defined on the Cayley cones $C_y(\mathfrak{D}^i)$.

DEFINITION 5.3. An *integral linear function* on \mathfrak{D}^i is a map $\vartheta: C(\mathfrak{D}^i) \rightarrow \mathbb{Q}$ such that

- (i) for every $y \in C^i$, there exist an $m_y \in M$ and a $b_y \in \mathbb{Z}$ such that for any $(\nu, \ell) \in C_y(\mathfrak{D}^i)$,

$$\vartheta(y, \nu, \ell) = \langle m_y, \nu \rangle + \ell c_y;$$

- (ii) if C^i is projective, there exist an $m \in M$ such that $m_y = m$ for any $y \in C$ and an $f \in \mathbb{C}(C)^*$ such that

$$\text{div } f = \sum_{y \in C} c_y \cdot [y].$$

Denote by $\mathcal{F}_{\mathcal{E}}$ the union of all the sets \mathcal{F}^i for $i \in J$. A *colored integral piecewise linear function* on \mathcal{E} is a pair $\theta = (\vartheta, (r_\alpha))$, where $\vartheta: |\mathcal{E}| \rightarrow \mathbb{Q}$ is a function such that the restriction $\vartheta|_{C(\mathfrak{D}^i)}$ is integral linear for every i in J and $\vartheta|_{C(\mathfrak{D}^i)}$ and $\vartheta|_{C(\mathfrak{D}^j)}$ coincide on $C(\mathfrak{D}^i) \cap C(\mathfrak{D}^j)$ for all i and j in J , and where (r_α) is a sequence of integers with α running over simple roots in $\Phi \setminus I$ such that $D_\alpha \notin \mathcal{F}_{\mathcal{E}}$. More generally, we say that $\theta = (\vartheta, (r_\alpha))$ is a *colored piecewise linear function*

on \mathcal{E} if there exists a $k \in \mathbb{Z}_{>0}$ such that $k\theta$ is a colored integral piecewise linear function. We denote by $\text{PL}(\mathcal{E})$ (respectively, $\text{PL}(\mathcal{E}, \mathbb{Q})$) the set of colored integral piecewise linear functions (respectively, colored piecewise linear functions) on \mathcal{E} .

Now, the Cartier divisor associated with a colored piecewise linear function θ in $\text{PL}(\mathcal{E})$ is

$$\begin{aligned} D_\theta = & \sum_{(y,p) \in \text{Vert}(\mathcal{E})} \vartheta(y, \kappa(p)p, \kappa(p)) D_{(y,p)} + \sum_{\rho \in \text{Ray}(\mathcal{E})} \vartheta(C, \rho, 0) D_\rho \\ & + \sum_{D \in \mathcal{F}_\mathcal{E}} \vartheta(C, \varrho(D), 0) D + \sum_{D_\alpha \notin \mathcal{F}_\mathcal{E}} r_\alpha D_\alpha. \end{aligned}$$

PROPOSITION 5.4 ([LT16, Corollary 2.19]). *The variety $X(\mathcal{E})$ is \mathbb{Q} -Gorenstein (that is, K_X is \mathbb{Q} -Cartier) if and only if there exists a $\theta = (\vartheta, (r_\alpha))$ in $\text{PL}(\mathcal{E}, \mathbb{Q})$ such that the following conditions are satisfied:*

- (i) *There exists a canonical divisor $K_C = \sum_{y \in C} b_y \cdot [y]$ on C where for every (y, p) in $\text{Vert}(\mathcal{E})$ we have*

$$\vartheta(y, \kappa(p)p, \kappa(p)) = \kappa(p)b_y + \kappa(p) - 1.$$

- (ii) *For every ρ in $\text{Ray}(\mathcal{E})$, we have $\vartheta(C, \rho, 0) = -1$.*

- (iii) *For every D_α in $\mathcal{F}_\mathcal{E}$, we have $\vartheta(C, \varrho(D_\alpha), 0) = -a_\alpha$.*

Let θ_X be the colored piecewise linear function on X satisfying the conditions of Proposition 5.4 and such that $r_\alpha = -a_\alpha$ for any α with $D_\alpha \notin \mathcal{F}_\mathcal{E}$. The uniqueness follows from [Tim11, Equations (17.1–2)].

The support function ϖ used in Theorem 5.16 is constructed by gluing the following linear functions.

LEMMA 5.5. *Let $(\mathfrak{D}, \mathcal{F})$ be a colored σ -polyhedral divisor on $(C, G/H)$ such that $Y = X(\mathfrak{D}, \mathcal{F})$ is \mathbb{Q} -Gorenstein. Let z be a point in the locus of \mathfrak{D} , and denote by $X(C_z(\mathfrak{D}), \mathcal{F})$ the horospherical $(G \times \mathbb{C}^*)$ -variety associated with the pair $(C_z(\mathfrak{D}), \mathcal{F})$ and the horospherical homogeneous space $G/H \times \mathbb{C}^*$. Then there exists a linear function $\omega_{Y,z}$ on $C_z(\mathfrak{D})$ such that*

- (i) $\omega_{Y,z}(\rho, 0) = \vartheta_Y(z, \rho, 0)$ for any uncolored ray ρ of σ ,
- (ii) $\omega_{Y,z}(\tau) = -1$ for any ray τ of $C_z(\mathfrak{D})$ not contained in $N_{\mathbb{Q}}$,
- (iii) $\omega_{Y,z}(\varrho(D_\alpha), 0) = -a_\alpha$ for any color $D_\alpha \in \mathcal{F}$.

In particular, if the locus of \mathfrak{D} is affine, we have

$$X(\mathfrak{D}, \mathcal{F}) \text{ } \mathbb{Q}\text{-Gorenstein} \Rightarrow X(C_z(\mathfrak{D}), \mathcal{F}) \text{ } \mathbb{Q}\text{-Gorenstein}.$$

Proof. As Y is \mathbb{Q} -Gorenstein, by Proposition 5.4 there exists, on $(\mathfrak{D}, \mathcal{F})$, a colored piecewise linear function $\theta_Y = (\vartheta_Y, (r_\alpha))$ satisfying the conditions (i)–(iii) of the proposition. We construct the function $\omega_{Y,z}$ by modifying θ_Y . To do so, we construct a function f in $\mathbb{C}(C)^*$ such that $-\text{ord}_z(f) = b_z + 1$ for any (z, p) in $\text{Vert}(\mathfrak{D})$, where $K_C = \sum_{y \in C} b_y \cdot [y]$ is a canonical divisor of C . Since C is smooth, any divisor on C is locally principal. Hence there exist an open neighborhood C' of z in C and a function f in $\mathbb{C}(C')^*$, which is equal to $\mathbb{C}(C)^*$, such that $(K_C + [z])|_{C'} = (\text{div } f^{-1})|_{C'}$. The divisor $D_{\theta_Y} + \text{div}(f)$ is a Cartier \mathbb{Q} -divisor in X . The restriction $\omega_{Y,z}$ of its support function to $C_z(\mathfrak{D})$ is the required function. Indeed, as required, using Proposition 5.4, we get

$$\omega_{Y,z}(\kappa(p)p, \kappa(p)) = \vartheta(z, \kappa(p)p, \kappa(p)) + \kappa(p) \text{ord}_z(f) = -1.$$

Let us now assume that the locus of \mathfrak{D} is affine. The variety $X(C_z(\mathfrak{D}), \mathcal{F})$ being horospherical, it is \mathbb{Q} -Gorenstein if and only if there exists a (restricted) linear function $\omega: C_z(\mathfrak{D}) \rightarrow \mathbb{Q}$ such that $\omega(\tau) = -1$ for any uncolored ray τ of $C_z(\mathfrak{D})$ (that is, $\tau \cap \varrho(\mathcal{F}) = \emptyset$) and $\omega(\varrho(D_\alpha), 0) = -a_\alpha$ for any color D_α in \mathcal{F} (see [Bri93, Proposition 4.1]). These conditions are satisfied by the function $\omega_{Y,z}$. Indeed, since the locus of \mathfrak{D} is affine, for any uncolored ray ρ of σ , we have $\omega_{Y,z}(\rho, 0) = \vartheta_Y(z, \rho, 0) = -1$. \square

In Theorem 5.16, we will need to assume that X is log terminal to ensure the convergence of the integral of the stringy motivic volume. We recall the following criterion.

THEOREM 5.6 ([LS13], [LT16, Theorem 2.22]). *Suppose that $X = X(\mathcal{E})$ is \mathbb{Q} -Gorenstein. Then X has only log terminal singularities if and only if for any $(\mathfrak{D}, \mathcal{F}) \in \mathcal{E}$, one of the following assertions holds:*

- (i) *The locus of \mathfrak{D} is affine.*
- (ii) *The locus of \mathfrak{D} is the projective line \mathbb{P}^1 and $\sum_{y \in \mathbb{P}^1} (1 - 1/\kappa_y) < 2$, where*

$$\kappa_y := \max(\{\kappa(p) \mid p \text{ is a vertex of } \Delta_y\}) .$$

Here the polyhedron Δ_y is defined by $\mathfrak{D} = \sum_{y \in C_0} \Delta_y \cdot [y]$.

5.3 Desingularization

Here we explain how to desingularize X in terms of combinatorial data. The desingularization involves three proper birational morphisms:

$$X(\mathcal{E}') \xrightarrow{q'} X(\tilde{\mathcal{E}}) \xrightarrow{q} X(\mathcal{E}_{\text{dis}}) \xrightarrow{\pi_{\text{dis}}} X(\mathcal{E}) = X . \tag{5.1}$$

ψ

The discoloration morphism π_{dis} and the affinization morphism q have already been defined in equations (3.5) and (4.2). Let us now construct the morphism q' . Let $\text{Sp}(\tilde{\mathcal{E}})$ be the set of special points of $\tilde{\mathcal{E}}$, and denote its elements by y_1, \dots, y_r . Up to refining the affine coverings $(C_j^i)_{j \in J_i}$ in the construction outlined in Notation 4.9, we may assume that each element of $\tilde{\mathcal{E}}$ contains at most one special point. For $1 \leq i \leq r$, we let $\tilde{\mathcal{E}}_i$ be the set of all polyhedral divisors \mathfrak{D} in $\tilde{\mathcal{E}}$ which have y_i as a special point, and we define a fan Σ_i on $N_{\mathbb{Q}} \oplus \mathbb{Q}$ as the fan generated by the Cayley cones $C_{y_i}(\mathfrak{D})$ for any \mathfrak{D} in $\tilde{\mathcal{E}}$. Clearly, the fans Σ_i all contain the tail fan $\Sigma(\tilde{\mathcal{E}})$ as a subfan. Now following [CLS11, Section 11.1], we will consider a star subdivision of $\Sigma(\tilde{\mathcal{E}})$ and compatible star subdivisions of the Σ_i .

DEFINITION 5.7. Consider a fan Σ in $N_{\mathbb{Q}}$ and an element ν of $|\Sigma| \cap N$ in the support of Σ . The *star subdivision* of Σ associated with ν is the fan consisting of the cones

- (i) $\sigma \in \Sigma$ such that $\nu \notin \sigma$,
- (ii) $\text{Cone}(\tau, \nu)$ for $\tau \in \Sigma$ such that $\nu \notin \tau$ and there exists a $\sigma \in \Sigma$ with $\{\nu\} \cup \tau \subset \sigma$.

A star subdivision is a subdivision of the original fan Σ (see [CLS11, Lemma 11.1.3]).

We say that a fan Σ is *smooth* if any cone in Σ is generated by a subset of a lattice basis of N . This is equivalent to the toric variety X_{Σ} being smooth. By [CLS11, Theorem 11.1.9], any fan Σ has a smooth refinement Σ' containing every smooth cone of Σ and obtained from Σ by a sequence

of star subdivisions. Geometrically, this implies that there is a projective desingularization of toric varieties $X_{\Sigma'} \rightarrow X_{\Sigma}$.

Let $\Sigma'(\tilde{\mathcal{E}})$ be a smooth refinement of the tail fan $\Sigma(\tilde{\mathcal{E}})$, corresponding to a sequence of star subdivisions associated with an element $(\nu_1, \dots, \nu_s) \in N^s$. For any $1 \leq i \leq r$, define $\hat{\Sigma}_i$ as the fan obtained from Σ after applying star subdivisions with respect to $((\nu_1, 0), \dots, (\nu_s, 0))$ in $(N \oplus \mathbb{Z})^s$. Clearly, $\Sigma'(\tilde{\mathcal{E}})$ is a smooth subfan of $\hat{\Sigma}_i$. Finally, there exists a refinement Σ'_i of $\hat{\Sigma}_i$ such that Σ'_i contains every smooth cone of $\hat{\Sigma}_i$, including in particular every cone of $\Sigma'(\tilde{\mathcal{E}})$.

For any \mathfrak{D} in $\tilde{\mathcal{E}}_i$, consider the set $\Sigma_{i,\mathfrak{D}}$ of cones τ in Σ'_i such that $\tau \subset C_{y_i}(\mathfrak{D})$. For $\tau \in \Sigma_{i,\mathfrak{D}}$, we denote by $\sigma_{\tau,i}$ the cone $\tau \cap (N_{\mathbb{Q}} \times \{0\})$ and by $\Delta_{\tau,i}$ the set $\tau \cap (N_{\mathbb{Q}} \times \{1\})$ when $\tau \not\subset N_{\mathbb{Q}} \times \{0\}$. Since $\tau \subset C_{y_i}(\mathfrak{D})$, it follows that $\tau \cap (N_{\mathbb{Q}} \times \{1\})$ is a $\sigma_{\tau,i}$ -polyhedron. We define a $\sigma_{\tau,i}$ -polyhedral divisor

$$\mathfrak{D}_{\tau,i} := \sum_{y \in C_0} \Delta_y \cdot [y],$$

where $C_0 \subset C$ is the locus of \mathfrak{D} and $\Delta_y = \sigma_{\tau,i}$ for any $y \in C_0 \setminus \{y_i\}$. In addition, $\Delta_{y_i} = \sigma_{\tau,i}$ if $\tau \subset N_{\mathbb{Q}} \times \{0\}$ and $\Delta_{y_i} = \Delta_{\tau,i}$ otherwise. The set $\tilde{\mathcal{E}}_{\mathfrak{D}} := \{\mathfrak{D}_{\tau,i} \mid \tau \in \Sigma_{i,\mathfrak{D}}\}$ is a divisorial fan. Moreover, the \mathbb{C} -algebras embeddings $A(C_0, \mathfrak{D}) \subset A(C_0, \mathfrak{D}_{\tau,i})$ for $\mathfrak{D}_{\tau,i} \in \tilde{\mathcal{E}}_{\mathfrak{D}}$ induce a proper T -equivariant birational morphism $V(\tilde{\mathcal{E}}_{\mathfrak{D}}) \rightarrow V(\mathfrak{D})$; see [Tim11, Theorem 12.13]. Since the set $\mathcal{E}' := \bigcup_{\mathfrak{D} \in \tilde{\mathcal{E}}} \tilde{\mathcal{E}}_{\mathfrak{D}}$ is a divisorial fan, the previous morphisms glue together into a proper birational morphism $q': X(\mathcal{E}') \rightarrow X(\tilde{\mathcal{E}})$. To prove that $X(\mathcal{E}')$ is indeed smooth, we use [KKMS73, Chapter II], [LS13, Proof of Proposition 2.6], and [LT16, Theorem 2.5].

This concludes our construction of the desingularization of X .

5.4 Discrepancy

The aim of this section is to compute the discrepancy of the G -equivariant morphism $\psi: X' \rightarrow X$ from equation (5.1), whose definition we recall below.

$$X' := X(\mathcal{E}') \xrightarrow{q'} X(\tilde{\mathcal{E}}) \xrightarrow{q} X(\mathcal{E}_{\text{dis}}) \xrightarrow{\pi_{\text{dis}}} X.$$

ψ

The exceptional divisors of ψ are particular G -divisors of X' ; that is, they correspond to some elements of $\text{Vert}(\mathcal{E}') \sqcup \text{Ray}(\mathcal{E}')$.

Exceptional divisors of π_{dis} . As $\text{Vert}(\mathcal{E}_{\text{dis}})$ is equal to $\text{Vert}(\mathcal{E})$, the exceptional divisors of π_{dis} are in one-to-one correspondence with the elements of $\text{Ray}(\mathcal{E}_{\text{dis}})$ which do not come from $\text{Ray}(\mathcal{E})$, that is, the elements of

$$\bigcup_{i \in J} \text{Ray}(\mathfrak{D}^i, \emptyset) \setminus \text{Ray}(\mathfrak{D}^i, \mathcal{F}^i). \tag{5.2}$$

By Lemma 5.5, the associated divisors $D_{\rho_1}, \dots, D_{\rho_t} \subset X(\mathcal{E}_{\text{dis}})$ in (5.2) are the exceptional divisors of π_{dis} .

Exceptional divisors of q . The morphism $q: X(\tilde{\mathcal{E}}) \rightarrow X(\mathcal{E}_{\text{dis}})$ is obtained via parabolic induction on the T -equivariant morphism $V(\tilde{\mathcal{E}}) \rightarrow V(\mathcal{E})$ from equation (4.2), so the exceptional divisors of q are the parabolic inductions of the exceptional divisors of the latter map. By [AH06, Theorem 10.1], the set $\text{Ray}(\tilde{\mathcal{E}}) \setminus \text{Ray}(\mathcal{E}_{\text{dis}})$ is equal to the union over all colored polyhedral divisors

$(\mathfrak{D}, \emptyset)$ in $\tilde{\mathcal{E}}$ with projective locus, of the rays ρ of the tails of polyhedral divisors \mathfrak{D} with the property $\deg \mathfrak{D} \cap \rho \neq \emptyset$. We denote the associated exceptional divisors of q by $D_{\rho_{t+1}}, \dots, D_{\rho_s} \subset X(\tilde{\mathcal{E}})$.

Exceptional divisors of q' . As before, the map $q': X' = X(\mathcal{E}') \rightarrow X(\tilde{\mathcal{E}})$ is obtained from the map $q'': V(\mathcal{E}') \rightarrow V(\tilde{\mathcal{E}})$. Denote by $\{y_1, \dots, y_u\}$ the set of special points of $\tilde{\mathcal{E}}$. For $1 \leq i \leq u$, consider the fans Σ_i and Σ'_i constructed in Section 5.3. The exceptional divisors of q'' (or, equivalently, of q') are in bijection with the triples $[y_i, \nu, \ell]$, where (ν, ℓ) is a ray of $\Sigma'_i \setminus \Sigma_i$. When $\ell = 0$, the triple $(y_i, \nu, 0)$ corresponds to an element of $\text{Ray}(\mathcal{E}')$; otherwise, it corresponds to an element of $\text{Vert}(\mathcal{E}')$. We denote the associated exceptional divisors by $D'_{\rho_{s+1}}, \dots, D'_{\rho_e}$ and $D'_{(y_1, p_1)}, \dots, D'_{(y_u, p_u)}$, respectively.

Relative canonical class of ψ . Since $\Sigma(\tilde{\mathcal{E}}) = \Sigma(\mathcal{E}_{\text{dis}}) = \Sigma(\mathcal{E})$ and $\Sigma(\mathcal{E}')$ is a fan subdivision of $\Sigma(\tilde{\mathcal{E}})$, we may identify the pullbacks of $D_{\rho_1}, \dots, D_{\rho_s}$ with the corresponding divisors $D'_{\rho_1}, \dots, D'_{\rho_s}$ in X' . By the previous paragraphs, the exceptional divisors of ψ are the $(D'_{\rho_i})_{1 \leq i \leq e}$ and the $(D'_{(y_j, p_j)})_{1 \leq j \leq u}$.

PROPOSITION 5.8. *If $X(\mathcal{E})$ is \mathbb{Q} -Gorenstein, then the relative canonical class of ψ is represented by*

$$K_{X'/X} = \sum_{j=1}^u (\kappa(p_j) b_{y_j} + \kappa(p_j) - 1 - \vartheta_X(y, \kappa(p_j) p_j, \kappa(p_j))) D'_{(y_j, p_j)} + \sum_{i=1}^e (-1 - \vartheta_X(C, \rho_i, 0)) D'_{\rho_i},$$

where $\sum_{y \in C} b_y \cdot [y]$ is a canonical divisor of C , $\theta_X = (\vartheta_X, (r_\alpha))$ is the support function from Section 5.2, and $\kappa: N_{\mathbb{Q}} \rightarrow \mathbb{Z}$ is defined by $\kappa(p) = \min\{\lambda \in \mathbb{Z}_{>0} \mid \lambda \cdot p \in N\}$.

Proof. A canonical divisor of X' is given by

$$K_{X'} = \sum_{(y,p) \in \text{Vert}(\mathcal{E}')} \vartheta_{X'}(y, \kappa(p)p, \kappa(p)) D'_{(y,p)} + \sum_{\rho \in \text{Ray}(\mathcal{E}')} \vartheta_{X'}(C, \rho, 0) D'_{\rho} - \sum_{\alpha \in \Phi \setminus I} a_{\alpha} D'_{\alpha},$$

while the pullback by ψ of a canonical divisor of X is

$$\psi^* K_X = \sum_{(y,p) \in \text{Vert}(\mathcal{E}')} \vartheta_X(y, \kappa(p)p, \kappa(p)) D'_{(y,p)} + \sum_{\rho \in \text{Ray}(\mathcal{E}')} \vartheta_X(C, \rho, 0) D'_{\rho} - \sum_{\alpha \in \Phi \setminus I} a_{\alpha} D'_{\alpha},$$

where we choose K_X as in Theorem 5.6. Hence

$$K_{X'/X} = \sum_{j=1}^u (\vartheta_{X'} - \vartheta_X)(y, \kappa(p_j) p_j, \kappa(p_j)) D'_{(y_j, p_j)} + \sum_{i=1}^e (\vartheta_{X'} - \vartheta_X)(C, \rho_i, 0) D'_{\rho_i}.$$

We conclude by computing the values of $\vartheta_{X'}$ using Proposition 5.4. □

5.5 Stringy invariants

This section is devoted to determining the stringy motivic volume of a log terminal horospherical variety of complexity one by using the discrepancy calculation from Section 5.4. We use the notation of that section and denote by $\Gamma \subset C$ an open dense affine subset which does not contain any special point. Let d be the dimension of X .

Decomposition of the motivic integral. We decompose the motivic volume $\mathcal{E}_{\text{st}}(X)$ along the fibers of the map $\underline{\text{val}}: X_{\Gamma}^t \rightarrow |\mathcal{E}'|_{\Gamma} \cap \mathcal{N}$ from equation (4.4). The next statement immediately follows from the measurability results of Lemmas 4.14 and 4.15.

LEMMA 5.9. *With the above notation, the stringy motivic volume can be decomposed as*

$$\mathcal{E}_{\text{st}}(X) = \sum_{(y, \nu, \ell) \in |\mathcal{E}'|_{\Gamma} \cap \mathcal{N}} \int_{\underline{\text{val}}^{-1}(y, \nu, \ell)} \mathbb{L}^{-\text{ord}_{K_{X'/X}}} d\mu_{X'}.$$

The stringy support function. Now we want to calculate the right-hand side of the identity in Lemma 5.9, depending on whether $\ell = 0$ or $\ell \geq 1$. As we did in Lemma 5.5 for a single hypercone, we need to introduce a new support function ω_X inspired by the definition of the function θ_X .

PROPOSITION-DEFINITION 5.10. *Denote by $(\mathfrak{D}^i, \mathcal{F}^i)$ the elements of \mathcal{E} for $i \in J$. There exists a pair $\varpi_X = (\omega_X, (r_{\alpha}))$, where $\omega_X: |\mathcal{E}| \rightarrow \mathbb{Q}$ is a function and $r_{\alpha} \in \mathbb{Z}$ for any $\alpha \in \Phi \setminus I$, such that*

- for any $i \in J$ and any y in the locus of \mathfrak{D}^i , we have
 - (i) $\omega_X(y, \rho, 0) = \vartheta_X(y, \rho, 0)$ for any uncolored ray ρ of the tail of \mathfrak{D}^i ,
 - (ii) $\omega_X(y, \tau) = -1$ for any ray τ of $C_y(\mathfrak{D}^i)$ not contained in $N_{\mathbb{Q}}$,
 - (iii) $\omega_X(y, \varrho(D_{\alpha}), 0) = -a_{\alpha}$ for any color $D_{\alpha} \in \mathcal{F}^i$,
 - (iv) $r_{\alpha} = -a_{\alpha}$ for any $\alpha \in \Phi \setminus I$ such that $D_{\alpha} \notin \mathcal{F}_{\mathcal{E}}$,
 - (v) $\omega_X(y, \nu, \ell) = \langle m_y^i, \nu \rangle + \ell c_y^i$ for some $m_y^i \in M$ and $c_y^i \in \mathbb{Q}$.
- If $(y, \nu, \ell) \in C(\mathfrak{D}^i) \cap C(\mathfrak{D}^j)$, then $\langle m_y^i, \nu \rangle + \ell c_y^i = \langle m_y^j, \nu \rangle + \ell c_y^j$.

We call the pair $\varpi_X = (\omega_X, (r_{\alpha}))$ the stringy support function.

Proof. Since X is \mathbb{Q} -Gorenstein, by Lemma 5.5, for any $i \in J$ and y in the locus of \mathfrak{D}^i , there exists a linear function $\omega_{i,y}$ on $C_y(\mathfrak{D}^i)$ satisfying conditions (i)–(iii) above. It is enough to check that $\omega_{i,y}$ and $\omega_{j,y}$ coincide on $C_y(\mathfrak{D}^i) \cap C_y(\mathfrak{D}^j)$. Indeed, $C_y(\mathfrak{D}^i) \cap C_y(\mathfrak{D}^j)$ is a common face to both $C_y(\mathfrak{D}^i)$ and $C_y(\mathfrak{D}^j)$. It is generated by colored or uncolored rays. Moreover, both $\omega_{i,y}$ and $\omega_{j,y}$ are linear on the common face and coincide on the rays, which concludes the proof. \square

Motivic volume for horizontal arcs. We compute the motivic integral over subsets of the form $\underline{\text{val}}^{-1}(C, \nu, 0)$.

LEMMA 5.11. *Let $(y, \nu, 0)$ be an element of $|\mathcal{E}'|_{\Gamma} = |\mathcal{E}|_{\Gamma}$. We have*

$$\int_{\underline{\text{val}}^{-1}(C, \nu, 0)} \mathbb{L}^{-\text{ord}_{K_{X'/X}}} d\mu_{X'} = [G/H][\Gamma] \mathbb{L}^{\vartheta_X(C, \nu, 0)}.$$

Proof. We only prove the result for a T -variety. The general case is obtained by parabolic induction. Let $\sigma \in \Sigma(\mathcal{E}')$ be a cone containing ν and \mathfrak{D} be a σ -polyhedral divisor of \mathcal{E}' with (affine) locus C_0 . The rays of σ either correspond to exceptional divisors of $\psi: X' \rightarrow X$ or are elements of $\text{Ray}(\mathcal{E})$. For the exceptional divisors, we use the notation of Section 5.4. Up to renumbering, we may assume that the exceptional rays of σ are ρ_1, \dots, ρ_a , and we denote the remaining rays by $\tau_{a+1}, \dots, \tau_r$. Write $V_{\mathbb{Q}} := \sigma^{\vee} \cap (-\sigma^{\vee})$, and choose a basis (v_1, \dots, v_{d-1-r}) of $V_{\mathbb{Q}} \cap M$. Let $u_1, \dots, u_a, u_{a+1}, \dots, u_r$ be the duals of $\rho_1, \dots, \rho_a, \tau_{a+1}, \dots, \tau_r$.

From [PS11, Remark 3.16(2)], we know that the ideal of a T -stable divisor D'_{ρ_j} is given by

$$I(D'_{\rho_j}) = \bigoplus_{m \in (\sigma^{\vee} \setminus \rho_j^{\perp}) \cap M} H^0(C_0, \mathcal{O}_{C_0}([\mathfrak{D}(m)])) \otimes \chi^m. \quad (5.3)$$

If $\alpha \in \underline{\text{val}}^{-1}(C, \nu, 0)$ and $f \otimes \chi^m$ is a homogeneous element of degree m in $A(C_0, \mathfrak{D})$, we have

$$\alpha^*(f \otimes \chi^m) = t^{\nu(m)} \omega(m) R(f),$$

where we use the notation of Remark 4.3. Hence $\sup \{k \in \mathbb{N} \mid \alpha^*(f \otimes \chi^m) \in (t^k)\} = \langle m, \nu \rangle$.

Write $\nu = \nu_1 \rho_1 + \dots + \nu_a \rho_a + \nu_{a+1} \tau_{a+1} + \dots + \nu_r \tau_r$. We have $\nu_i \in \mathbb{N}$ for $1 \leq i \leq r$. An element m of $(\sigma^\vee \setminus \rho_j^\perp) \cap M$ can be decomposed as $m = m_1 u_1 + \dots + m_r u_r + m'_1 v_1 + \dots + m'_{d-1-r} v_{d-1-r}$ with $m_i \in \mathbb{N}$ for $1 \leq i \leq r$, $m_j \neq 0$, and m'_1, \dots, m'_{d-1-r} in \mathbb{Z} . Hence $\langle m, \nu \rangle = \sum_{i=1}^r m_i \langle u_i, \nu \rangle$. Finally, we have

$$\min \{ \langle m, \nu \rangle \mid m \in (\sigma^\vee \setminus \rho_j^\perp) \cap M \} = \langle u_j, \nu \rangle.$$

We have $\text{ord}_{D'_{\rho_j}} \alpha = \langle u_j, \nu \rangle$ and $\text{ord}_{D'_{(y_i, p_i)}} \alpha = 0$ since $\alpha \in \underline{\text{val}}^{-1}(C, \nu, 0)$. We obtain

$$\text{ord}_{K_{X'/X}}(\alpha) = \sum_{i=1}^a (-1 - \vartheta_X(C, \rho_i, 0)) \langle u_i, \nu \rangle. \quad (5.4)$$

Now by equation (5.4) and Theorem 4.16, we get

$$\begin{aligned} \int_{\underline{\text{val}}^{-1}(C, \nu, 0)} \mathbb{L}^{-\text{ord}_{K_{X'/X}} d\mu_{X'}} &= \mu_{X'}(\underline{\text{val}}^{-1}(C, \nu, 0)) \mathbb{L}^{\sum_{i=1}^a (1 + \vartheta_X(C, \rho_i, 0)) \langle u_i, \nu \rangle} \\ &= [\Gamma][G/H] \mathbb{L}^{-\sum_{j=1}^r \langle u_j, \nu \rangle + \sum_{i=1}^a (1 + \vartheta_X(C, \rho_i, 0)) \langle u_i, \nu \rangle}. \end{aligned}$$

By the linearity of ϑ_X on each Cayley cone and the decomposition of ν on the integral basis, we obtain

$$\vartheta_X(C, \nu, 0) = \sum_{i=1}^a \langle u_i, \nu \rangle \vartheta_X(C, \rho_i, 0) + \sum_{j=a+1}^r \langle u_j, \nu \rangle \vartheta_X(C, \tau_j, 0).$$

Finally, by the definition of ϑ_X , we have $\vartheta_X(C, \tau_j, 0) = -1$ for $a+1 \leq j \leq r$, which concludes the proof. \square

COROLLARY 5.12. *With the notation of Lemma 5.11, we have*

$$\int_{\underline{\text{val}}^{-1}(C, \nu, 0)} \mathbb{L}^{-\text{ord}_{K_{X'/X}} d\mu_{X'}} = [G/H][\Gamma] \mathbb{L}^{\omega_X(C, \nu, 0)}.$$

Motivic volume for vertical arcs. We now consider motivic integrals over vertical components of the arc space $\mathcal{L}_\Gamma(X')$. Let $\xi = (y, \nu, \ell)$ be an element of $|\mathcal{E}^\ell|_\Gamma \cap \mathcal{N}$ such that $\ell \geq 1$. As in the previous lemma, we assume $G = T$ and $H = \{e\}$. Let \mathfrak{D} be a polyhedral divisor of \mathcal{E}^ℓ with (affine) locus C_0 such that $(\nu, \ell) \in C_y(\mathfrak{D})$, and denote by σ the tail of \mathfrak{D} . Let r be the dimension of σ and s be the dimension of $C_y(\mathfrak{D})$. Up to renumbering the exceptional divisors of Section 5.4, we may assume that the rays of σ either correspond to exceptional divisors $D'_{\rho_1}, \dots, D'_{\rho_a}$ of $\psi: X' \rightarrow X$ or are elements $\tau_{a+1}, \dots, \tau_r$ of $\text{Ray}(\mathcal{E})$. Similarly, the other rays

$$\lambda_1 := (\kappa(p_1)p_1, \kappa(p_1)), \dots, \lambda_{s-r} := (\kappa(p_{s-r})p_{s-r}, \kappa(p_{s-r}))$$

of $C_y(\mathfrak{D})$ include those associated with the exceptional divisors $D'_{(y, p_1)}, \dots, D'_{(y, p_u)}$.

Let $\Lambda = M \oplus \mathbb{Z}$. Write $V_{\mathbb{Q}} := C_y(\mathfrak{D})^\vee \cap (-C_y(\mathfrak{D})^\vee)$, and choose a basis (v_1, \dots, v_{d-s}) of $V_{\mathbb{Q}} \cap \Lambda$. Let $u_1, \dots, u_a, u_{a+1}, \dots, u_r$ be the duals of $\rho_1, \dots, \rho_a, \tau_{a+1}, \dots, \tau_r$ in N and w_1, \dots, w_{s-r} be the duals of $\lambda_1, \dots, \lambda_{s-r}$. A set of generators of the semigroup $C_y(\mathfrak{D})^\vee \cap \Lambda$ is given by

$$(u_1, 0), \dots, (u_r, 0); \pm v_1, \dots, \pm v_{d-s}; w_1, \dots, w_{s-r}.$$

LEMMA 5.13. *We have*

$$\int_{\underline{\text{val}}^{-1}(\xi)} \mathbb{L}^{-\text{ord}_{K_{X'/X}} d\mu_{X'}} = [G/H](\mathbb{L} - 1) \mathbb{L}^{\vartheta_X(\xi) - \sum_{i=1}^{s-r} (\kappa(p_i)b_y + \kappa(p_i)) \langle w_i, (\nu, \ell) \rangle}.$$

Proof. Let π in $\mathbb{C}(C)^*$ be a uniformizer of y . Recalling the expression of the ideal $I(D'_{\rho_j})$ from equation (5.3), we can compute $\text{ord}_{D'_{\rho_j}}(\alpha)$ by studying $\alpha^*(\pi^k \otimes \chi^m)$ for all (m, k) in $(C_y(\mathfrak{D})^\vee \setminus (\rho_j, 0)^\perp) \cap \Lambda$. We may then use the same argument as in Lemma 5.11. We obtain $\text{ord}_{D'_{\rho_j}}(\alpha) = \langle u_j, \nu \rangle$ for any α in $\underline{\text{val}}^{-1}(\xi)$. Let us now recall the description of $I(D'_{(y, p_i)})$ from [PS11, Remark 3.16(1)]:

$$I(D'_{(y, p_i)}) = \bigoplus_{m \in \sigma^\vee \cap M} H^0(C_0, \mathcal{O}_{C_0}([\mathfrak{D}(m)])) \cap \{f \in \mathbb{C}(C_0) \mid \text{ord}_y f + \langle m, p_i \rangle > 0\} \otimes \chi^m.$$

As before, we can compute $\text{ord}_{D'_{(y, p_i)}}(\alpha)$ from the computation of $\alpha^*(\pi^k \otimes \chi^m)$ for any pair (m, k) in $(C_y(\mathfrak{D})^\vee \setminus (p_i, 1)^\perp) \cap \Lambda$. We find $\text{ord}_{D'_{(y, p_i)}}(\alpha) = \langle w_i, (\nu, \ell) \rangle$. Then it follows from Proposition 5.8 that

$$\text{ord}_{K_{X'/X}}(\alpha) = \sum_{j=1}^a c_j \langle u_j, \nu \rangle + \sum_{i=1}^{s-r} d_i \langle w_i, (\nu, \ell) \rangle, \quad (5.5)$$

where $c_j = -1 - \vartheta_X(C, \rho_j, 0)$ and $d_i = \kappa(p_i)b_y + \kappa(p_i) - 1 - \vartheta_X(y, \kappa(p_i)p_i, \kappa(p_i))$. Note that $d_i = 0$ for $u < i \leq s - r$. Now by equation (5.5) and Theorem 4.16,

$$\begin{aligned} \int_{\underline{\text{val}}^{-1}(\xi)} \mathbb{L}^{-\text{ord}_{K_{X'/X}} d\mu_{X'}} &= \mu_{X'}(\underline{\text{val}}^{-1}(\xi)) \mathbb{L}^{-\sum_{j=1}^a c_j \langle u_j, \nu \rangle - \sum_{i=1}^{s-r} d_i \langle w_i, (\nu, \ell) \rangle} \\ &= [G/H](\mathbb{L} - 1) \mathbb{L}^{-\sum_{j=1}^r \langle u_j, \nu \rangle - \sum_{i=1}^{s-r} \langle w_i, (\nu, \ell) \rangle - \sum_{j=1}^a c_j \langle u_j, \nu \rangle - \sum_{i=1}^{s-r} d_i \langle w_i, (\nu, \ell) \rangle}. \end{aligned}$$

Since ϑ_X is linear on Cayley cones, decomposing ν on the integral basis, we conclude using the identity

$$\begin{aligned} \vartheta_X(\xi) - \sum_{i=1}^{s-r} (\kappa(p_i)b_y + \kappa(p_i)) \langle w_i, (\nu, \ell) \rangle &= \sum_{j=1}^a (-1 - c_j) \langle u_j, \nu \rangle - \sum_{j=a+1}^r \langle u_j, \nu \rangle \\ &\quad - \sum_{i=1}^{s-r} (1 + d_i) \langle w_i, (\nu, \ell) \rangle. \quad \square \end{aligned}$$

To rephrase the formula of Lemma 5.13 in terms of the function ω_X , we need the following.

PROPOSITION 5.14. *Let \mathcal{E} be a colored divisorial fan on $(C, G/H)$. Assume that $X := X(\mathcal{E})$ is \mathbb{Q} -Gorenstein, and let $X' = X(\mathcal{E}')$ be the desingularization of X as defined in equation (5.1). Then for any (y, p) in $\text{Vert}(\mathcal{E}') \setminus \text{Vert}(\mathcal{E})$, we have $(\vartheta_{X'} - \vartheta_X)(y, \kappa(p)p, \kappa(p)) = -1 - \omega_X(y, \kappa(p)p, \kappa(p))$.*

Proof. Since the problem is local, we may assume $\mathcal{E} = \{(\mathfrak{D}, \mathcal{F})\}$. We first show the statement when $\mathcal{E} = \tilde{\mathcal{E}}$, that is, when the coloration \mathcal{F} is trivial and the locus C_0 of \mathfrak{D} is affine. By parabolic induction, we may also assume $G = T$ and $H = \{e\}$. Write

$$\mathfrak{D} = \sum_{z \in C_0} \Delta_z \cdot [z],$$

and let $y \in C_0$. Set $\mathcal{E}^i = \{\mathfrak{D}^i\}_{i \in J}$. The cones $C_y(\mathfrak{D}^i)$ generate a fan Σ' in $N_{\mathbb{Q}} \oplus \mathbb{Q}$. Denote by X_{tor} (respectively, by X'_{tor}) the toric $(T \times \mathbb{C}^*)$ -variety associated with the cone $C_y(\mathfrak{D}) \subset N_{\mathbb{Q}} \oplus \mathbb{Q}$ (respectively, with the fan Σ'). By Lemma 5.5, we know that X_{tor} is \mathbb{Q} -Gorenstein. Moreover,

X'_{tor} is smooth, and the proper birational map $X'_{\text{tor}} \rightarrow X_{\text{tor}}$ is a $(T \times \mathbb{C}^*)$ -equivariant resolution of singularities.

Define a σ -polyhedral divisor $\hat{\mathfrak{D}}$ with locus \mathbb{A}^1 on (\mathbb{P}^1, T) by setting $\hat{\mathfrak{D}} := \sum_{z \in \mathbb{A}^1} \hat{\Delta}_z \cdot [z]$, where

$$\hat{\Delta}_z = \begin{cases} \Delta_y & \text{if } z = 0, \\ \sigma & \text{otherwise.} \end{cases}$$

Similarly, for any $i \in J$, we define a polyhedral divisor $\hat{\mathfrak{D}}^i$ with locus \mathbb{A}^1 associated with \mathfrak{D}^i , and we let $\hat{\mathcal{E}}^i$ be the corresponding divisorial fan. We have a commutative diagram

$$\begin{array}{ccc} X'_{\text{tor}} & \xrightarrow{q'} & X_{\text{tor}} \\ \parallel & & \parallel \\ X(\hat{\mathcal{E}}^i) & \xrightarrow{q'} & X(\hat{\mathfrak{D}}^i). \end{array}$$

Indeed, the equality on the right comes from the description of the \mathbb{C} -algebra $A(\mathbb{A}^1, \hat{\mathfrak{D}})$ viewed as the semigroup algebra $\mathbb{C}[C_0(\hat{\mathfrak{D}})^\vee \cap (M \oplus \mathbb{Z})]$. The other equality is similar.

Consider the support functions $\theta_X = (\vartheta_X, (-a_\alpha))$ in $\text{PL}(\mathfrak{D})$ and $\theta_{X'} = (\vartheta_{X'}, (-a_\alpha))$ in $\text{PL}(\mathcal{E}')$ satisfying the hypotheses of Proposition 5.4, which induce functions on, respectively, $C_y(\mathfrak{D})$ and Σ' . To prove the proposition, we compute the discrepancy of q' in two different ways.

Let us first compute the discrepancy of $q': X(\hat{\mathcal{E}}^i) \rightarrow X(\hat{\mathfrak{D}}^i)$ using the functions $\vartheta_{X'}$ and ϑ_X . By definition, the Weil \mathbb{Q} -divisor

$$\begin{aligned} \hat{K} &:= \sum_{(0,p) \in \text{Vert}(\hat{\mathcal{E}}^i) \setminus \text{Vert}(\hat{\mathfrak{D}}^i)} (\vartheta_{X(\hat{\mathcal{E}}^i)} - \vartheta_{X(\hat{\mathfrak{D}}^i)})(0, \kappa(p)p, \kappa(p)) D'_{(0,p)} \\ &\quad + \sum_{\rho \in \text{Ray}(\hat{\mathcal{E}}^i) \setminus \text{Ray}(\hat{\mathfrak{D}}^i)} (\vartheta_{X(\hat{\mathcal{E}}^i)} - \vartheta_{X(\hat{\mathfrak{D}}^i)})(\mathbb{P}^1, \rho, 0) D'_\rho \\ &= \sum_{(y,p) \in \text{Vert}(\mathcal{E}^i) \setminus \text{Vert}(\mathfrak{D}^i)} (\vartheta_{X'} - \vartheta_X)(y, \kappa(p)p, \kappa(p)) D'_{(0,p)} \\ &\quad + \sum_{\rho \in \text{Ray}(\mathcal{E}^i) \setminus \text{Ray}(\mathfrak{D}^i)} (\vartheta_{X'} - \vartheta_X)(C, \rho, 0) D'_\rho \end{aligned}$$

is a relative canonical divisor. Next, we compute the discrepancy of $q': X'_{\text{tor}} \rightarrow X_{\text{tor}}$ using the function ω_X . By [BM13, Proposition 4.2], the Weil \mathbb{Q} -divisor

$$K := \sum_{(y,p) \in \text{Vert}(\mathcal{E}^i) \setminus \text{Vert}(\mathfrak{D}^i)} (-1 - \omega_X(y, \kappa(p)p, \kappa(p))) D'_{(0,p)} + \sum_{\rho \in \text{Ray}(\mathcal{E}^i) \setminus \text{Ray}(\mathfrak{D}^i)} (-1 - \omega_X(y, \rho, 0)) D'_\rho$$

is a relative canonical divisor. The divisors K and \hat{K} are linearly equivalent. By [KM98, Lemma 3.39], we know that they are in fact equal. Thus

$$-1 - \omega_X(y, \kappa(p)p, \kappa(p)) = (\vartheta_{X(\hat{\mathcal{E}}^i)} - \vartheta_{X(\hat{\mathfrak{D}}^i)})(0, \kappa(p)p, \kappa(p)) \quad (5.6)$$

for any $(y, p) \in \text{Vert}(\mathcal{E}^i) \setminus \text{Vert}(\mathfrak{D}^i)$, which concludes the case where $\mathcal{E} = \tilde{\mathcal{E}}$.

For the case where \mathcal{E} is general, we remark that the functions $\omega_{X(\tilde{\mathcal{E}})} + \vartheta_X - \vartheta_{X(\tilde{\mathcal{E}})}$ and ω_X coincide. Indeed, they are linear on each Cayley cone of \mathcal{E} , and they have the same values on

the rays. Hence, taking this into account, we obtain equation (5.6) in the general case, which concludes the proof. \square

COROLLARY 5.15. *With the notation of Lemma 5.13, when $\ell \geq 1$, we have*

$$\int_{\text{val}^{-1}(y, \nu, \ell)} \mathbb{L}^{-\text{ord}_{K_{X'/X}}} d\mu_{X'} = [G/H](\mathbb{L} - 1) \mathbb{L}^{\omega_X(y, \nu, \ell)}.$$

Proof. We proved in Lemma 5.13 that

$$\int_{\text{val}^{-1}(y, \nu, \ell)} \mathbb{L}^{-\text{ord}_{K_{X'/X}}} d\mu_{X'} = [G/H](\mathbb{L} - 1) \mathbb{L}^{\vartheta_X(y, \nu, \ell) - \sum_{i=1}^{s-r} (\kappa(p_i) b_y + \kappa(p_i)) \langle w_i, (\nu, \ell) \rangle}. \quad (5.7)$$

By the definitions of $\vartheta_{X'}$ and ϑ_X , we have

$$\vartheta_X(y, \nu, \ell) - \sum_{i=1}^{s-r} (\kappa(p_i) b_y + \kappa(p_i)) \langle w_i, (\nu, \ell) \rangle = (\vartheta_X - \vartheta_{X'})(y, \nu, \ell) - \sum_{i=1}^r \langle \nu, u_i \rangle - \sum_{j=1}^r \langle (\nu, \ell), w_j \rangle.$$

Moreover, by linearity,

$$\begin{aligned} (\vartheta_X - \vartheta_{X'})(y, \nu, \ell) &= \sum_{i=1}^r \langle \nu, u_i \rangle (\vartheta_X - \vartheta_{X'})(y, \rho_i, 0) \\ &\quad + \sum_{j=1}^{s-r} \langle (\nu, \ell), w_j \rangle (\vartheta_X - \vartheta_{X'})(y, \kappa(p_j) p_j, \kappa(p_j)). \end{aligned} \quad (5.8)$$

By the proofs of Corollary 5.12 and Proposition 5.14, we have

$$(\vartheta_X - \vartheta_{X'})(y, \rho_i, 0) = \omega_X(y, \rho_i, 0) - 1$$

and

$$(\vartheta_X - \vartheta_{X'})(y, \kappa(p_j) p_j, \kappa(p_j)) = 1 + \omega_X(y, \kappa(p_j) p_j, \kappa(p_j)).$$

We obtain

$$(\vartheta_X - \vartheta_{X'})(y, \nu, \ell) - \sum_{i=1}^r \langle \nu, u_i \rangle - \sum_{j=1}^{s-r} \langle (\nu, \ell), w_j \rangle = \omega_X(y, \nu, \ell). \quad (5.9)$$

Replacing the exponent of \mathbb{L} on the right-hand side of equation (5.7) by $\omega_X(y, \nu, \ell)$ using equations (5.8) and (5.9), we obtain the stated result. \square

The stringy motivic volume

THEOREM 5.16. *Let \mathcal{E} be a colored divisorial fan on $(C, G/H)$ such that $X = X(\mathcal{E})$ is \mathbb{Q} -Gorenstein with log terminal singularities. Then for any open dense subset Γ in $C \setminus \text{Sp}(\mathcal{E})$, we have*

$$\mathcal{E}_{\text{st}}(X) = [G/H] \sum_{(y, \nu, \ell) \in |\mathcal{E}|_{\Gamma \cap \mathcal{N}}} [X_\ell] \mathbb{L}^{\omega_X(y, \nu, \ell)},$$

where $X_0 = \Gamma$ and $X_\ell = \mathbb{A}^1 \setminus \{0\}$ if $\ell \geq 1$. The stringy E -function of X is computed as follows:

$$E_{\text{st}}(X; u, v) = E(G/H; u, v) \sum_{(y, \nu, \ell) \in |\mathcal{E}|_{\Gamma \cap \mathcal{N}}} E(X_\ell; u, v) (uv)^{\omega_X(y, \nu, \ell)},$$

where $E(X_\ell; u, v) = E(\Gamma; u, v)$ if $\ell = 0$, else $E(X_\ell; u, v) = uv - 1$.

Proof. This follows from Lemma 5.9 and Corollaries 5.12 and 5.15. \square

Rational form and candidate poles. We end this section by giving a rational expression of the stringy motivic volume $\mathcal{E}_{\text{st}}(X)$ in terms of the combinatorial data \mathcal{E} . For a special point y in $\text{Sp}(\mathcal{E})$, we denote by \mathcal{E}_y the fan generated by the Cayley cones of the form $C_y(\mathfrak{D}^i)$, where $i \in J$. Let τ belong to \mathcal{E}_y . Fix a fan Σ_τ with support τ such that every cone of Σ_τ is simplicial and the cones of dimension one in Σ_τ are exactly the faces of dimension one of τ . Such a fan always exists (see [Ewa96, Section V.4]).

For an arbitrary polyhedral cone $\lambda \subset N_{\mathbb{Q}} \oplus \mathbb{Q}$, we denote by $\lambda(1)$ the set of primitive generators in $N \oplus \mathbb{Z}$ of the rays of λ . The *fundamental parallelotope* of λ is the set

$$P_\lambda := \left\{ \sum_{\rho \in \lambda(1)} \mu_\rho \rho \in N \oplus \mathbb{Z} \mid 0 \leq \mu_\rho < 1, \rho \in \lambda(1) \right\} \subset N_{\mathbb{Q}}.$$

We denote the set of proper faces of λ by the symbol $\text{Prop}(\lambda)$. For an element $v \in N \oplus \mathbb{Z}$, we write χ^v for the Laurent monomial associated with v . We define two functions L_1 and L_2 via the equalities

$$L_1(\gamma) := \left(\sum_{v \in P_\gamma} \chi^v \right) \prod_{\rho \in \tau(1) \setminus \gamma(1)} (1 - \chi^\rho) \quad \text{and} \quad L_2(\gamma) := L_1(\gamma) - \sum_{\gamma' \in \text{Prop}(\gamma)} L_1(\gamma')$$

for every cone $\gamma \in \Sigma_\tau$. We also introduce $Q(\tau, \Sigma_\tau) := \sum_{\gamma \in \Sigma_\tau \setminus \text{Prop}(\tau)} L_2(\gamma)$.

THEOREM 5.17. *Let $\tau \subset N_{\mathbb{Q}} \oplus \mathbb{Q}$ be a strongly convex, simplicial polyhedral cone. Then*

$$\sum_{u \in \tau \cap N \oplus \mathbb{Z}} \chi^u = \frac{\sum_{n \in P_\tau} \chi^n}{\prod_{\rho \in \tau(1)} (1 - \chi^\rho)}.$$

Proof. This follows from the proof of Gordan's lemma; see [CLS11, Proposition 1.2.17] and [Bri88, Section 2]. □

We give an interpretation of the polynomial $Q(\tau, \Sigma_\tau)$ in terms of the generating function

$$S(\tau) = \sum_{u \in \tau^\circ \cap (N \oplus \mathbb{Z})} \chi^u,$$

where τ° is the relative interior of τ .

LEMMA 5.18. *With the same notation as above,*

$$S(\tau) = Q(\tau, \Sigma_\tau) \prod_{\rho \in \tau(1)} (1 - \chi^\rho)^{-1}.$$

The polynomial $Q(\tau, \Sigma_\tau)$ does not depend on the choice of Σ_τ ; it will be denoted by $Q(\tau)$.

LEMMA 5.19. *Let \mathfrak{D} be a proper σ -polyhedral divisor on \mathbb{P}^1 . For any ray ρ of σ such that $\text{deg}(\mathfrak{D}) \cap \rho \neq \emptyset$, there exist a $\lambda \in \mathbb{Q}_{>0}$ and a vertex $v \in \text{deg}(\mathfrak{D})$ such that $\rho = \lambda v$.*

Proof. Straightforward. □

Using the combinatorial description of the log terminal condition given in Theorem 5.6, we study the sign of ω_X on each cone of the fan \mathcal{E}_y , where y is a special point of \mathcal{E} .

LEMMA 5.20. *Let $\tau \in \mathcal{E}_y$ and $\rho \in \tau(1)$. Then $\omega_X(y, \rho) < 0$.*

Proof. Consider $(\mathfrak{D}, \mathcal{F}) \in \mathcal{E}$ such that ρ is a primitive generator of a ray of $C_y(\mathfrak{D})$. First, assume $\rho \in \sigma(1)$, where σ is the tail of \mathfrak{D} . If $\rho \in \text{Ray}(\mathcal{E})$ or if a color of \mathcal{F} is mapped onto the ray $\mathbb{Q}_{\geq 0}\rho$, then by Proposition 5.10, the rational number $\omega_X(y, \rho)$ is negative. Otherwise, by Theorem 5.6, the log terminal condition implies that the locus of \mathfrak{D} is the projective line \mathbb{P}^1 and that $\text{deg}(\mathfrak{D}) \cap \mathbb{Q}_{\geq 0}\rho \neq \emptyset$. By Lemma 5.19, there exists a vertex v of $\text{deg}(\mathfrak{D})$ such that $\rho = \mu v$ for some $\mu \in \mathbb{Q}_{>0}$.

Let us write $\mathfrak{D} = \sum_{z \in \mathbb{P}^1} \Delta_z \cdot [z]$. Then (see Definition 5.3) we can find $e \in M$, $\alpha \in \mathbb{Q}_{>0}$, and $f \in \mathbb{C}(\mathbb{P}^1)^*$ such that for any $z \in \mathbb{P}^1$ and any vertex v in Δ_z , we have

$$\theta_X(z, \kappa(v)v, \kappa(v)) = \alpha \kappa(v) (\langle e, v \rangle + \text{ord}_z(f)) = \kappa(v)b_z + \kappa(v) - 1, \tag{5.10}$$

where $K_{\mathbb{P}^1} = \sum_{z \in \mathbb{P}^1} b_z \cdot [z]$ is a canonical divisor. Let $(v_z)_{z \in \mathbb{P}^1}$ be a sequence of elements of $N_{\mathbb{Q}}$ such that for any $z \in \mathbb{P}^1$, the element v_z is a vertex of Δ_z and $v = \sum_{z \in \mathbb{P}^1} v_z$. By equation (5.10) and Proposition 5.10, we obtain

$$\begin{aligned} \omega_X(C, v, 0) &= \sum_{z \in \mathbb{P}^1} \frac{1}{\alpha \kappa(v_z)} (\kappa(v_z) (\langle e, v_z \rangle + \text{ord}_z(f))) \\ &= \frac{1}{\alpha} \left(\text{deg } K_{\mathbb{P}^1} + \sum_{z \in \mathbb{P}^1} \left(1 - \frac{1}{\kappa(v_z)} \right) \right) < 0. \end{aligned} \tag{5.11}$$

The inequality is a consequence of the fact that $\text{deg } K_{\mathbb{P}^1} = -2$ and of the log terminal assumption on X (see Theorem 5.6). If ρ does not belong to $N_{\mathbb{Q}}$, then $\rho = (\kappa(w)w, \kappa(w))$ for some vertex w of Δ_y , and finally $\omega_X(y, \rho) = \theta_X(y, \kappa(w)w, \kappa(w)) = -1$. \square

COROLLARY 5.21. *Let $y \in \text{Sp}(\mathcal{E})$ be a special point, and let $\tau \in \mathcal{E}$. Let $\mathbb{C}[[\tau \cap (N \oplus \mathbb{Z})]]$ be the formal completion of the ring $\mathbb{C}[\tau \cap (N \oplus \mathbb{Z})]$ with respect to the ideal I_τ generated by the set $\{\chi^v \mid v \in \tau \cap (N \oplus \mathbb{Z}) \setminus \{0\}\}$. Elements of I_τ are of the form $\sum_{v \in \tau \cap (N \oplus \mathbb{Z})} a_v \chi^v$ with $a_v \in \mathbb{C}$. Let $m := \min\{a \in \mathbb{Z}_{>0} \mid a \cdot \omega_X \text{ takes its values in } \mathbb{Z}\}$. Then the map*

$$\varphi_\tau : (\mathbb{C}[\tau \cap (N \oplus \mathbb{Z})], I_\tau) \rightarrow (\mathbb{C}[\mathbb{L}^{-1/m}], \mathbb{L}^{-1/m} \mathbb{C}[\mathbb{L}^{-1/m}]), \quad \chi^v \mapsto \mathbb{L}^{\omega_X(y,v)}$$

is a well-defined, continuous morphism, and therefore it extends to the formal completions

$$\bar{\varphi}_\tau : \mathbb{C}[[\tau \cap (N \oplus \mathbb{Z})]] \rightarrow \mathbb{C}[[\mathbb{L}^{-1/m}]], \quad \chi^v \mapsto \mathbb{L}^{\omega_X(y,v)}.$$

Proof. By Lemma 5.20, we have $\varphi_\tau(I_\tau) \subset \mathbb{L}^{-1/m} \mathbb{C}[\mathbb{L}^{-1/m}]$, and $\bar{\varphi}_\tau$ exists [Mat80, Section 23.H]. \square

Inspired by the theory of Stanley–Reisner rings (see also [BM13, Section 6]), we introduce the following notion.

DEFINITION 5.22. Let $y \in \text{Sp}(\mathcal{E})$, and consider $\tau \in \mathcal{E}_y$. Let $m \in \mathbb{Z}_{>0}$ be as in Corollary 5.21. According to that corollary, we have $\bar{\varphi}_\tau(Q(\tau)) \in \mathbb{Z}[t^{-1}]$, where $t = \mathbb{L}^{1/m}$ and $Q(\tau) = Q(\tau, \Sigma_\tau)$ is the function of Lemma 5.18. The *Stanley–Reisner polynomial* associated with the pair (τ, ω_X) is the polynomial

$$P(\tau, \omega_X) := P(\tau, \omega_X)(t) = \mathbb{L}^{\eta(\tau, \omega_X)} \cdot \bar{\varphi}_\tau(Q(\tau)) \in \mathbb{Z}[t],$$

where $\eta(\tau, \omega_X) \in \frac{1}{m}\mathbb{Z}$ is the degree of $P(\tau, \omega_X)$ divided by m .

The following result describes a rational form of the stringy motivic volume $\mathcal{E}_{\text{st}}(X)$ in terms of the function ω_X .

THEOREM 5.23. *For every $y \in \mathrm{Sp}(\mathcal{E})$, let us denote by \mathcal{E}_y^* the set of cones τ of \mathcal{E}_y such that $\tau \not\subset N_{\mathbb{Q}}$. Let $\Gamma = C \setminus \mathrm{Sp}(\mathcal{E})$, and consider the tail fan $\Sigma(\mathcal{E})$ of \mathcal{E} . Then the stringy motivic volume of $X = X(\mathcal{E})$ is*

$$\begin{aligned} \mathcal{E}_{\mathrm{st}}(X) &= [G/H][\Gamma] \sum_{\tau \in \Sigma(\mathcal{E})} P(\tau, \omega_X) \mathbb{L}^{-\eta(\tau, \omega_X)} \prod_{\rho \in \tau(1)} (1 - \mathbb{L}^{\omega_X(C, \rho, 0)})^{-1} \\ &\quad + [G/H](\mathbb{L} - 1) \sum_{y \in \mathrm{Sp}(\mathcal{E})} \sum_{\tau \in \mathcal{E}_y^*} P(\tau, \omega_X) \mathbb{L}^{-\eta(\tau, \omega_X)} \prod_{\rho \in \tau(1)} (1 - \mathbb{L}^{\omega_X(y, \rho)})^{-1}, \end{aligned}$$

where $P(\tau, \omega_X)$ is the Stanley–Reisner polynomial associated with the pair (τ, ω_X) .

Proof. This follows from Theorem 5.16 and Corollary 5.21. \square

As a consequence of the theorem, under some assumptions on \mathcal{E} , we also obtain a formula for the stringy Euler characteristic of the variety X .

COROLLARY 5.24. *Let (M, I) be the pair describing the horospherical homogeneous space G/H . Consider $W := N_G(Q)/Q$, the Weyl group of (G, Q) , and $W_I \subset W$, the subset defined in Section 3.1. Let $r := \dim(N_{\mathbb{Q}})$. Assume that for every tail cone $\tau \in \Sigma(\mathcal{E})$ and every $\tau' \in \mathcal{E}_y$ for $y \in \mathrm{Sp}(\mathcal{E})$, we have $r \geq |\tau(1)|$ and $r + 1 \geq |\tau'(1)|$. Then*

$$\begin{aligned} \frac{|W_I|}{|W|} e_{\mathrm{st}}(X) &= e(\Gamma) \sum_{\tau \in \Sigma(\mathcal{E}), \dim(\tau)=r} P(\tau, \omega_X)(1) \prod_{\rho \in \tau(1)} \frac{1}{(-\omega_X(C, \rho, 0))} \\ &\quad + \sum_{y \in \mathrm{Sp}(\mathcal{E})} \sum_{\tau \in \mathcal{E}_y^*, \dim(\tau)=r+1} P(\tau, \omega_X)(1) \prod_{\rho \in \tau(1)} \frac{1}{(-\omega_X(y, \rho))}, \end{aligned}$$

where $P(\tau, \omega_X)$ is the Stanley–Reisner polynomial associated with the pair (τ, ω_X) .

6. Stringy Euler characteristic and a smoothness criterion

In this section, we start in Section 6.1 by illustrating Theorem 5.16 on the example of a hypersurface endowed with a $(\mathbb{C}^*)^2$ -action, which was initially studied by Liendo and Süß [LS13, Example 1.1]. Then, analogously to [BM13, Theorem 5.3], in Section 6.2 we deduce from Theorem 5.16 a smoothness criterion for locally factorial, horospherical varieties of complexity one.

6.1 An example where the acting group is a torus

Let $N = \mathbb{Z}^2$ and $\sigma = \mathrm{Cone}((1, 0), (1, 6)) \subset N_{\mathbb{Q}} = \mathbb{Q}^2$. Define a σ -polyhedral divisor on $(\mathbb{P}^1, (\mathbb{C}^*)^2)$ by $\mathfrak{D} = \sum_{y \in \mathbb{P}^1} \Delta_y \cdot [y]$, where

$$\Delta_y = \begin{cases} \mathrm{Conv}((1, 0), (1, 1)) + \sigma & \text{if } y = 0, \\ (-\frac{1}{2}, 0) + \sigma & \text{if } y = 1, \\ (-\frac{1}{3}, 0) + \sigma & \text{if } y = \infty, \\ \sigma & \text{otherwise.} \end{cases}$$

Figure 1 shows Δ_0 , Δ_1 , and Δ_{∞} .

The variety $X(\mathfrak{D})$ is a hypersurface in \mathbb{A}^4 , given by the equation $x_2^3 - x_3^2 + x_1 x_4 = 0$, where the $(\mathbb{C}^*)^2$ -action is given by

$$(\lambda_1, \lambda_2) \cdot (x_1, x_2, x_3, x_4) = (\lambda_2 x_1, \lambda_1^2 x_2, \lambda_1^3 x_3, \lambda_1^6 \lambda_2^{-1} x_4).$$

FIGURE 1. The σ -polyhedra Δ_0 , Δ_1 , and Δ_∞

An easy computation shows that the stringy motivic volume of $X(\mathfrak{D})$ is

$$\mathcal{E}_{\text{st}}(X) = \frac{\mathbb{L}(\mathbb{L} - 1)^2}{(1 - \mathbb{L}^{-5})^2} (1 - 2\mathbb{L}^{-1} + 3\mathbb{L}^{-2} + 3\mathbb{L}^{-3} + 4\mathbb{L}^{-4} + 10\mathbb{L}^{-5} - 10\mathbb{L}^{-6} + 15\mathbb{L}^{-7} + 3\mathbb{L}^{-8} + 2\mathbb{L}^{-9} + \mathbb{L}^{-10}).$$

Thus $e_{\text{st}}(X) = 6/5 > e(X) = 1$.

6.2 Stringy Euler characteristic and a smoothness criterion

LEMMA 6.1. *Let $(\mathfrak{D}, \mathcal{F})$ be a colored σ -polyhedral divisor on $(C, G/H)$ with affine locus C_0 . Assume that $X(\mathfrak{D})$ is locally factorial (that is, that any Weil divisor is Cartier) and that σ has dimension $\dim X - 1$. Then the stringy Euler characteristic is equal to*

$$e_{\text{st}}(X) = e(C_0) \frac{|W|}{|W_I| \prod_{D_\alpha \in \mathcal{F}} a_\alpha},$$

where, as usual, W denotes the Weyl group of (G, Q) and W_I denotes the Weyl group of $(N_G(H), Q)$.

Proof. Let $\Gamma \subset C_0 \setminus \text{Sp}(\mathfrak{D})$ be an open subset. By Theorem 5.16, we have

$$\begin{aligned} \mathcal{E}_{\text{st}}(X) &= [\Gamma][G/H] \sum_{\nu \in \sigma \cap N} \mathbb{L}^{\omega_X(C, \nu, 0)} + (\mathbb{L} - 1)[G/H] \sum_{y \in C_0 \setminus \Gamma} \sum_{(\nu, \ell) \in C_y(\mathfrak{D}) \setminus (\sigma \times \{0\})} \mathbb{L}^{\omega_X(y, \nu, \ell)} \\ &= [\Gamma] \mathcal{E}_{\text{st}}(X(\sigma, \mathcal{F})) + \sum_{y \in C_0 \setminus \Gamma} (\mathcal{E}_{\text{st}}(X(C_y(\mathfrak{D}), \mathcal{F})) - (\mathbb{L} - 1) \mathcal{E}_{\text{st}}(X(\sigma, \mathcal{F}))), \end{aligned}$$

where $X(\sigma, \mathcal{F})$ (respectively, $X(C_y(\mathfrak{D}), \mathcal{F})$) is the G -equivariant (respectively, $G \times \mathbb{C}^*$ -equivariant) embedding of the horospherical homogeneous space G/H (respectively, $G/H \times \mathbb{C}^*$) associated with the colored cone (σ, \mathcal{F}) (respectively, $(C_y(\mathfrak{D}), \mathcal{F})$). Here the last equality comes from [BM13, Theorem 4.3].

Passing to the stringy E -polynomial and evaluating at $u = v = 1$, we obtain

$$e_{\text{st}}(X) = e(\Gamma) e_{\text{st}}(X(\sigma, \mathcal{F})) + \sum_{y \in C_0 \setminus \Gamma} e_{\text{st}}(X(C_y(\mathfrak{D}), \mathcal{F})).$$

Using [BM13, Proposition 5.11], we see that $e_{\text{st}}(X(C_y(\mathfrak{D})), \mathcal{F}) = e_{\text{st}}(X(\sigma, \mathcal{F}))$ since the stringy Euler characteristic depends only on the Weyl groups and the colors, which are unchanged. We deduce

$$e_{\text{st}}(X) = e(C_0)e_{\text{st}}(X(\sigma, \mathcal{F})) \quad \text{and} \quad e_{\text{st}}(X(\sigma, \mathcal{F})) = \frac{|W|}{|W_I| \prod_{D_\alpha \in \mathcal{F}} a_\alpha},$$

which concludes the proof. \square

The following proposition gives a full description of the G -orbits of a simple G -model of $C \times G/H$ corresponding to a colored σ -polyhedral divisor $(\mathfrak{D}, \mathcal{F})$ with affine locus C_0 . For the complexity zero case, we refer to [BM13, Proposition 2.4].

PROPOSITION 6.2. *Let $(\mathfrak{D}, \mathcal{F})$ be a colored σ -polyhedral divisor on $(C, G/H)$ with affine locus C_0 . Then $X := X(\mathfrak{D}, \mathcal{F})$ has two types of G -orbits:*

- (i) horizontal orbits, which are contained in the G -invariant open subset $\Gamma \times X(\sigma, \mathcal{F})$ of X , where $\Gamma = C_0 \setminus \text{Sp}(\mathfrak{D})$ and $X(\sigma, \mathcal{F})$ is the G/H -embedding associated with the colored cone (σ, \mathcal{F}) ;
- (ii) vertical orbits, which are the remaining G -orbits.

Moreover, the horizontal G -orbits of X are parametrized by triples $(y, \tau, \mathcal{F}_\tau)$, where $y \in \Gamma$, τ is a face of σ , and $\mathcal{F}_\tau = \{D \in \mathcal{F} \mid \varrho(D) \in \tau\}$. The stabilizer $H_{y, \tau, \mathcal{F}_\tau} =: H_\tau$ of such a triple is given by

$$H_\tau = \{g \in P_{I_{\mathcal{F}_\tau}} \mid \chi^m(g) = 1 \text{ for any } m \in \tau^\perp \cap M\},$$

where $I_{\mathcal{F}_\tau} \subset \Phi$ is the union with I of the set of simple roots indexing the colors in \mathcal{F}_τ and χ^m is the character of $P_{I_{\mathcal{F}_\tau}}$ associated with m . Finally, the vertical G -orbits of X are parametrized by triples (y, F, \mathcal{F}_F) , where $y \in \text{Sp}(\mathfrak{D})$, F is a face of the σ -polyhedron Δ_y of \mathfrak{D} associated with y , and $\mathcal{F}_F = \{D_\alpha \in \mathcal{F} \mid \varrho(D_\alpha) \in \lambda(F)\}$ with

$$\lambda(F) = \{m \in M_\mathbb{Q} \mid \langle m, v - v' \rangle \geq 0 \text{ for any } v \in \Delta_y, v' \in F\}.$$

The stabilizer $H_{y, F, \mathcal{F}_F} =: H_{y, F}$ of a triple (y, F, \mathcal{F}_F) is given by $H_{y, F} = \{g \in P_{I_{\mathcal{F}_F}} \mid \forall m \in M_y, \chi^m(g) = 1\}$ with

$$M_y = \left\{ m \in M \cap \lambda(F) \cap (-\lambda(F)) \mid \min_{v \in \Delta_y} \langle m, v \rangle \in \mathbb{Z} \right\}.$$

Proof. This follows by combining [BM13, Proposition 2.4] and [AH06, Section 7]. \square

We compute the (usual) Euler characteristic and compare it to the stringy version of Lemma 6.1.

LEMMA 6.3. *Under the same assumptions as in Lemma 6.1, the Euler characteristic of X is*

$$e(X) = e(C_0) \frac{|W|}{|W_{I_{\mathcal{F}}}|}.$$

Proof. We have a decomposition $e(X) = e(\Gamma \times X(\sigma, \mathcal{F})) + \sum_{O \text{ vertical } G\text{-orbit}} e(O)$ by Proposition 6.2. Using [BM13, Proposition 5.11] and the parametrization of vertical orbits given in Proposition 6.2, we obtain

$$e(X) = e(\Gamma) \frac{|W|}{|W_{I_{\mathcal{F}}}|} + \sum_{y \in \text{Sp}(\mathfrak{D})} \sum_{v \in \Delta_y} \frac{|W|}{|W_{I_{\mathcal{F}_{\{v\}}}}|}.$$

Thus it only remains to prove that

$$\frac{|W|}{|W_{I_{\mathcal{F}}}|} = \sum_{v \in \Delta_y} \frac{|W|}{|W_{I_{\mathcal{F}\{v\}}}|}. \quad (6.1)$$

Fix a point $y_0 \in C_0$, and define a colored σ -polyhedral divisor $(\hat{\mathcal{D}}, \mathcal{F})$ on $(\mathbb{P}^1, G/H)$ with $\hat{\mathcal{D}} := \sum_{z \in \mathbb{A}^1} \hat{\Delta}_z \cdot [z]$, where $\hat{\Delta}_z = \Delta_{y_0}$ if $z = 0$ and $\hat{\Delta}_z = \sigma$ otherwise. The variety $X(\hat{\mathcal{D}})$ is locally factorial and horospherical, and it identifies with the $(G \times \mathbb{C}^*)$ -equivariant embedding of $G/H \times \mathbb{C}^*$ associated with the colored cone $(C_0(\hat{\mathcal{D}}), \mathcal{F}) = (C_{y_0}(\mathcal{D}), \mathcal{F})$. Thus by [BM13, Proposition 5.11], we obtain

$$\frac{|W|}{|W_{I_{\mathcal{F}}}|} = e(X(C_0(\hat{\mathcal{D}}), \mathcal{F})) = e(X(\hat{\mathcal{D}})) = e(\mathbb{C}^*)e(X(\sigma, \mathcal{F})) + \sum_{v \in \Delta_y} \frac{|W|}{|W_{I_{\mathcal{F}\{v\}}}|}.$$

Since $e(\mathbb{C}^*) = 0$, this proves equation (6.1) and concludes the proof. \square

Combining Lemmas 6.1 and 6.3 with the smoothness criterion of [LT16, Theorem 2.5], we obtain the following result.

THEOREM 6.4. *Let $(\mathcal{D}, \mathcal{F})$ be a colored σ -polyhedral divisor on $(C, G/H)$ with affine locus $C_0 \subset C$. Assume that $X = X(\mathcal{D})$ is locally factorial and that for any $y \in C_0$, the Cayley cone $C_y(\mathcal{D})$ has dimension $d = \dim X$. Then we have $e_{\text{st}}(X) \geq e(X)$. Moreover, if $2 - 2g - |C \setminus C_0| \neq 0$, then X is smooth if and only if $e_{\text{st}}(X) = e(X)$.*

ACKNOWLEDGEMENTS

The authors would like to thank Anne-Sophie Kaloghiros, Hendrik Süß, Willem Veys, and Takehiko Yasuda for useful discussions.
