Integrating Specifications: Development Relations and Correspondences

Eerke Boiten

Computer Science Department

University of Kent at Canterbury

INT @ ETAPS 2002

Research area & approach

- Viewpoint Specification (*partial specification*)
- Formal Methods (Z, CSP, →UML)
- Open Distributed Processing framework
- Consistency & Unification

- Cross Viewpoint Consistency in ODP
- ODP Viewpoints in a Development Framework
- A Constructive Framework for Partial Specification
- with John Derrick, Marius Bujorianu and others

E.A.Boiten@ukc.ac.uk

Integration vs. Consistency

- *Integration* of two descriptions:
  a single description that faithfully represents both
- *Consistency* of two descriptions:
  posing no contradictory requirements
- *Unification* of two descriptions:
  combination of their requirements
  = constructive consistency = integration

- *Integration* of description *formalisms* = ...

E.A.Boiten@ukc.ac.uk

Dimensions of consistency

	Structural	Behavioural
Homogeneous	*Solved* (modules static semantics)	*Solvable* per language
Heterogeneous	*Solved* (case tools)	*Difficult!*

E.A.Boiten@ukc.ac.uk

Homogeneous Behavioural Integration

- Model/implementation based: integration = common implementation.
- Disadvantages: not abstract, not incremental, not relevant (feedback!)
- Alternative: use *development relations*

E.A.Boiten@ukc.ac.uk

Homogeneous Development Relations

- "refinement" relations, often predefined
- normally pre-orders: transitive & reflexive
- possibly from models/implementations:
  x develops *y* iff $Models(x) \subseteq Models(y)$
- unification = ("greatest") lower bound
- consistency = $\exists$ unification

E.A.Boiten@ukc.ac.uk

Not Quite as Homogeneous …

- Multiple development relations for single notation, e.g. process algebra
- Pairs (*spec*, ≤) as primitive partial specifications
- Unification, consistency still possible
- Can embed into single development relation

- Assumption: shared interface, unrealistic

E.A.Boiten@ukc.ac.uk

Correspondences

- (ODP) Linking viewpoints
- Meta-level, structural: for every X in spec. 1, there should be a matching Y in spec. 2.
- Spec. level: which Y matches a particular X?

- Primitive: give X and Y same name
- Qualified naming
- Data dictionary

E.A.Boiten@ukc.ac.uk

Interface or Internals?

- Some names in a specification belong to interface
- Other names do not belong to observable behaviour

- Correspondence relating interfaces: stable
- Correspondence relating internals: mutable
- Correspondence relations: names + … … …

E.A.Boiten@ukc.ac.uk

Integration & Correspondence

- Dependent on shape of correspondences in the language
- Correspondence becomes part of integrated specification:
- E.g. data dictionary ∃-quantified
- Equivalences and other functional correspondences lead to substitutions
- Consistency depends on correspondence

E.A.Boiten@ukc.ac.uk

On to Heterogeneity …

- Still pairs ($spec_i$, dev_i)
- Definition of integration, consistency: same.
- Consequence: dev_i need common co-domain. (Common semantics/implementation.)

- Correspondence: bridges formalisms!
- Must relate interfaces. How?

E.A.Boiten@ukc.ac.uk

Heterogeneous Correspondences

- Correspondences must operate on common level?

- If $dev_i = dv_i$; $trans_i$ for homogeneous dv_i (all i) then correspondences can be at specification level. (Internals related $\Leftrightarrow$ preserved by $trans_i$)

- Can also embed this into homogeneous model.

E.A.Boiten@ukc.ac.uk

General Abstract Nonsense?

- Integration *only* possible if preservation of requirements ensured.
- Preservation of requirements must be verifiable: either directly (refinement) or indirectly (comparing semantics).
- Inclusion of requirements at semantic level is the *definition* of refinement.
  Unavoidable!

E.A.Boiten@ukc.ac.uk

Applications

- Z, process algebra, and combinations

- UML?
- Structural consistency OK.
- Main issue: notion of implementation /-conformance for *all* included notations.
- Development “for free”.

E.A.Boiten@ukc.ac.uk

Practical Approaches

- Component approach: a component refined by every system which includes it and utilises it according to contract.
- Layered approach: templates. Templates refined by every consistent instantiation.
- Both lead to obvious integration and simple consistency check.
- But: aspects/viewpoints/non-functional requirements mantra: cheap not always possible.

E.A.Boiten@ukc.ac.uk

Abstract Approach

- Defining a high-level common semantics for a large collection of languages. (Category theory, institutions, transformation systems?)
- Translations into semantics (injective?)
- Investigating language properties and features that make partial specification feasible, constructive, practical. (Pushouts, pullbacks, order preserving translations, …)

Conclusions

- No silver bullet
- Integration of formalisms: identify semantics, refinement, translation, correspondence, interfaces. (Many inter-relations.)
- Framework, vocabulary?

E.A.Boiten@ukc.ac.uk
