34 **Author contributions**

35 T.S., M.J.S., E.M. and K.A.W. conceived the idea. T.S. designed the study, processed the socioeconomic  
36 and environmental data, and performed the analyses. M.J.S. coordinated the project, and obtained funding  
37 with E.M. and K.A.W. K.M.C. and H.G. provided the concessions data. E.A.L., F.A.V.S.J., C.L.M. and M.A.  
38 assisted with the socioeconomic and environmental datasets. T.S. and M.J.S. led the manuscript, which was  
39 critically reviewed and edited by the other authors. All authors contributed to the interpretation of analyses  
40 and gave final approval for publication.

41 **Abstract**

42 The Roundtable on Sustainable Palm Oil (RSPO) has emerged as the leading sustainability certification  
43 system to tackle socio-environmental issues associated with the oil palm industry. To date, the effectiveness  
44 of RSPO certification for achieving its socioeconomic objectives remains uncertain. We evaluate the impact of  
45 certification on village-level well-being across Indonesia by applying counterfactual analysis to multi-  
46 dimensional government poverty data. We compare poverty across 36,311 villages between 2000 and 2018,  
47 tracking changes from before oil palm plantations were first established to several years after plantations  
48 were certified. Certification was associated with reduced poverty in villages with primarily market-based  
49 livelihoods, but not with those in which subsistence livelihoods were dominant before switching to oil palm.  
50 We highlight the importance of baseline village livelihood systems in shaping local impacts of agricultural  
51 certification, and assert that oil palm certification in certain village contexts may require additional resources  
52 to ensure socioeconomic objectives are realised.

53 **Main**

54 Oil palm cultivation has expanded tremendously in response to global demand for oils and fats over the last  
55 three decades. In 2018, the crop covers around 19 million hectares of land across the tropics, and a further  
56 10-14 million hectares is likely needed in this region to satisfy projected global demand in 2050<sup>1</sup>. In the same  
57 year, Indonesia was the world's largest palm oil producer, supplying more than 40 million tonnes of crude  
58 palm oil, or 56% of global production<sup>2</sup>. The country's oil palm plantation area has tripled since 2000 and now  
59 covers 14 million hectares, greater than the area of Java<sup>2</sup>. Unlike other key agricultural commodities in  
60 Indonesia where farms are largely managed by smallholders, the ownership of Indonesian oil palm  
61 plantations is mostly through private corporations<sup>2</sup> (Extended Data Figure 1).

62 The continuing expansion of oil palm across tropical countries has prompted fierce national and  
63 international debate<sup>3,4</sup>. While governments, industry lobbies, and companies have pointed to regional  
64 economic development and rural poverty alleviation to justify expansion of the oil palm sector<sup>4-6</sup>, numerous  
65 social and environmental costs of the industry have also been reported. These include land conflicts<sup>7-9</sup>, loss  
66 of forest<sup>10</sup>, biodiversity<sup>1</sup> and traditional livelihoods and culture<sup>8,11</sup>, water scarcity and pollution<sup>12-14</sup>, increased  
67 flooding<sup>15</sup>, and heightened risk of fire and concomitant emissions, especially due to expansion of plantations  
68 on peatland<sup>16-19</sup>. In response to these sustainability concerns, the Roundtable on Sustainable Palm Oil  
69 (RSPO) was formed in 2004 as a multi-stakeholder participatory body that promotes more sustainable  
70 production, in part by offering a sustainability certification system<sup>20</sup>. In 2019, around 4 million hectares of oil  
71 palm plantations had been certified, equating to ~20% of the global area cultivated<sup>21</sup>. Certified plantations are  
72 predominantly managed by companies (90%<sup>21</sup>), although there has been pressure on the RSPO to enable  
73 greater smallholder participation<sup>22</sup>.

74 Despite 15 years of promoting more sustainable production practices, the effectiveness of RSPO  
75 certification in delivering social and environmental benefits to local communities in producing areas remains  
76 uncertain<sup>23,24</sup>. Mixed impacts of certification have been reported by several studies based on counterfactual  
77 evidence comparing the performance of certified and similar non-certified concessions<sup>25-29</sup>. Few if any such  
78 robust evaluations have addressed social aspects beyond basic financial measures, mainly because of a lack  
79 of systematic socioeconomic data availability over large spatial and temporal scales. In addition, past social  
80 evaluations have not fully accounted for the substantial heterogeneity in baseline village conditions, such as  
81 socioeconomic and sociocultural characteristics, which may result in misleading assessments of certification  
82 outcomes<sup>30,31</sup>. Indeed, numerous sociology and development studies provide evidence for the widespread

83 failures of development programmes based on modernization approaches and technologies applied to  
84 agriculture without adequately considering resource barriers to local communities, institutional and  
85 infrastructural constraints, and cultural values<sup>32,33</sup> (see Supplementary Methods 1 for further discussion).

86 Here we evaluate the impact of RSPO certification on village well-being across the main oil palm  
87 producing regions of Indonesia: Sumatra (land area of 470,000 km<sup>2</sup>; comprising 24,259 villages or *Desa*),  
88 Kalimantan (540,000 km<sup>2</sup>; 7,095 villages), and Papua (420,000 km<sup>2</sup>; 4,957 villages) (Figure 1). Of the total  
89 36,311 villages sampled across the three islands, we identified 2,602 villages with large-scale non-certified oil  
90 palm plantations (i.e. those with at least 10% of the land area allocated to non-certified industrial plantations –  
91 the median amount across the whole region) and 794 villages with large-scale RSPO-certified plantations (i.e.  
92 ≥10% of the village land area allocated to RSPO-certified plantations). We define village-level well-being in  
93 line with the Sustainable Livelihood Approach<sup>34-35</sup> in terms of the socioeconomic (i.e., living conditions,  
94 infrastructure, and income support) and socioecological (i.e., security, social equity, and natural hazard  
95 prevention) capabilities of people to function in society (Supplementary Table 1 and Supplementary Methods  
96 2). Poverty arises when these capabilities break down<sup>36</sup>. We applied rigorous counterfactual analysis based  
97 on statistical matching methods to address three research questions: (1) How have oil palm and RSPO  
98 certification expanded in Indonesia in the context of ongoing rural development and agrarian transition?; (2)  
99 What have been the impacts of oil palm and subsequent RSPO certification on village-level well-being?; and  
100 (3) What lessons can be learned from how these impacts have been generated in relation to changing land-  
101 use, livelihoods, and community composition?

102 To answer these questions, we tracked changes in 18 socioeconomic and socioecological well-being  
103 indicators throughout the certification process, starting before plantations were first established to several  
104 years after plantations were certified. We derived these well-being indicators together with information on  
105 primary livelihood sectors from a large longitudinal dataset of village-level censuses - *Potensi Desa* (PODES)  
106 or 'Village Potential' - collected by Indonesia's Bureau of Statistics (BPS) roughly every three years between  
107 2000 and 2018<sup>37</sup>. By incorporating the latest census in 2018, we evaluated poverty change in 587 villages 5-  
108 11 years after the development of industrial oil palm plantations and 500 villages 5-11 years after the  
109 issuance of RSPO oil palm certificates, thereby providing insights on how impacts manifest as land is first  
110 converted to oil palm and then later certified. This nuanced assessment of how the characteristics of the oil  
111 palm industry evolve over time in a particular location is rarely addressed in other studies.

## 112 **Regional variation in oil palm and RSPO certification**

113 The pace of development in Indonesia's oil palm industry has been unevenly distributed. Most development  
114 has occurred in Sumatra (now 81,200 km<sup>2</sup>) (Figure 1a and Extended Data Figure 2), with the island being the  
115 oldest centre of oil palm production. The industry then expanded eastward across the major regions of  
116 Kalimantan (53,300 km<sup>2</sup>) (Figure 1b and Extended Data Figure 3) and more recently Papua (2,100 km<sup>2</sup>)  
117 (Figure 1c and Extended Data Figure 4). In Sumatra, the extent of oil palm plantations nearly doubled since  
118 2000, while Kalimantan and Papua experienced a near-fourfold increase in production area over the same  
119 period (Figure 1 and Extended Data Figures 2-4). The three regions can be viewed as being at advanced,  
120 intermediate, and early stages of oil palm development, respectively. These distinct development stages are  
121 broadly reflective of the expansion of the crop pan-tropically. For example, Malaysia and Thailand are also at  
122 an advanced stage of oil palm development, while the industry is still in its infancy across Latin America<sup>1</sup>.

123 The developmental context in Sumatra, Kalimantan, and Papua is also reflected in patterns of  
124 plantation ownership. In Indonesia, cultivation of more than 25 hectares of croplands by a single farmer or  
125 entity requires a concession permit (*Izin Usaha Perkebunan* or IUP), issued by the head of a regency, mayor,  
126 or governor (Ministerial Decree No. 98/Permentan/2013). In Sumatra, between 2000 and 2018, oil palm  
127 plantations (i.e. planted oil palm) are largely dominated by non-concession holders (64% for NCONC), which  
128 mostly represent smallholders (68%) and medium to large-scale industrial plantations with unknown  
129 concession status (32%, Supplementary Figure 1). There, the rate of plantation expansion outside of known  
130 concession boundaries (NCONC) has exceeded that within large-scale concessions, i.e., non-certified  
131 industrial oil palm plantations (CONC) and RSPO-certified industrial plantations (CERT) (Figure 1a and  
132 Extended Data Figure 2). Conversely, over the same period, large-scale industrial plantations have  
133 dominated oil palm expansion in Kalimantan and Papua (66% for CONC and CERT combined in Kalimantan  
134 and 69% for CONC in Papua) (Figures 1b-c and Extended Data Figures 3-4).

135 Analysis of the primary land-use or cover in villages between 2000 and 2018 indicates that those with  
136 ≥10% of village land area under industrial oil palm plantation in 2018 but <10% of area in industrial oil palm in  
137 2000 experienced a typical sequence of land-use prior to oil palm development (Figure 2a and Extended  
138 Data Figure 5). In 2000, 23% of these villages were primarily forested, and timber was frequently  
139 commercially harvested<sup>38</sup> resulting in degraded forest stands. These villages were then transformed to  
140 agricultural lands, mixed plantations and shrubs, then to (non-certified) industrial oil palm plantations. Some  
141 of the existing (non-certified) oil palm plantations were later granted RSPO certification. Conversion from  
142 forest to certified plantations had rarely occurred (Extended Data Figure 5).

143        Each of these land-uses is associated with specific livelihood systems and community composition  
144        (i.e. ethnicity) within village boundaries defined in the PODES census. Based on data from 2000, 2005, 2011  
145        and 2018 across villages in Sumatra, Kalimantan, and Papua, those villages with high natural forest cover  
146        were typically dominated by subsistence-based communities (i.e. subsistence farming, fishing, and forest  
147        product gathering, in complex agroforestry systems and with weak exposure to the market economy) and  
148        comprised a high proportion of people belonging to ethnic groups native to the island (Figure 3). Villages with  
149        agricultural lands, mixed plantations and shrubs as the primary land-use or cover typically had a larger  
150        proportion of agricultural plantation communities, mainly polyculture smallholders (with some exposure to the  
151        market system<sup>30,31</sup>), and larger proportions of ethnic groups from other islands who are likely recent migrants  
152        (Figure 3). Villages with non-certified oil palm plantations as the primary land-use had substantially larger  
153        proportions of their community working in plantation agriculture, where monoculture oil palm was the norm  
154        (with stronger market-driven orientation<sup>30,31</sup>), and large proportions of migrants (Figure 3). In villages  
155        dominated by the RSPO-certified plantations, monoculture oil palm plantation communities and migrants  
156        were also prominent (Figure 3). Thus, primary land-use transition is likely to have significant social  
157        implications for village communities through changes in livelihood systems and social structure (Figure 2b).  
158        These transitions are not necessarily unidirectional; for example, if oil palm fails, the system can return to  
159        mixed plantations and shrubs. We do not consider such transitions away from oil palm here.

160        Rural development has traditionally been, and often still is, pushed by governments to achieve  
161        development targets measured mostly through economic material attainment (i.e. large industry and  
162        manufacturing, and the market-based economy), rather than on improving underlying human-capital (i.e.  
163        capability and adaptation of technology within local culture, knowledge, and outlook)<sup>39</sup>. Relying heavily on  
164        industry and market-driven systems to meet development targets can result in immense social costs to rural  
165        communities because doing so allows little opportunity and time for people to adapt<sup>40</sup>. Kalimantan exemplifies  
166        this type of rapid development over the last two decades, as evident from the high prevalence (52%) of  
167        villages experiencing drastic change in dominant land-use from high natural forest cover to primarily oil palm  
168        monoculture (41%) and from forest to certified plantations (11%) between 2000 and 2018 (Figure 4a).  
169        Comparatively, in Sumatra and Papua 88% of villages with industrial oil palm plantations or certified  
170        plantations as the primary land-use in 2018 were already dominated by industrial monoculture plantations in  
171        2000 (Figure 4a).

172        Land-use changes in villages shifting to industrial oil palm plantations (Figure 4a) reflect an  
173        underlying pattern of oil palm development and expansion in Indonesia. Papua represents an early stage of

174 the oil palm industry, where plantation development is mainly confined within former or current transmigration  
175 villages and operated mostly by large oil palm companies<sup>41</sup> (Figure 4a and Extended Data Figure 4).  
176 Kalimantan represents the intermediate stage of industrial oil palm development, where company plantations  
177 have expanded rapidly into villages in forested landscapes that are dominated by subsistence-based  
178 communities (Figure 4a and Extended Data Figure 3). These expansions lead to an influx of workers and  
179 stimulate spontaneous migrations to the newly opened oil palm areas<sup>42</sup>. At this intermediate stage, oil palm  
180 smallholdings also expand, but the expansion rate is slower than the industrial-scale plantations (Extended  
181 Data Figure 3). Sumatra represents the advanced stage of oil palm development, where the number of  
182 smallholders, who either migrated in the preceding intermediate stage or more recently, continues to grow  
183 and expand exceeding the rate of expansion of the company plantations (Figure 4a and Extended Data  
184 Figure 2). This in turn creates a complex company and smallholder relationship<sup>43,44</sup>. The intermediate stage  
185 of oil palm development that occurred over the last two decades in Kalimantan (Figure 4b) generated swift  
186 radical transformation in village life systems in many parts of the island which often led to conflict<sup>30,31</sup>. Based  
187 on the PODES data, during this transformation period, social conflicts were 22% more prevalent in villages  
188 with industrial oil palm plantation development compared to those without, and such conflicts were more  
189 prevalent in Kalimantan than in Sumatra and Papua (Supplementary Figure 2).

## 190 **Impacts of oil palm and certification on well-being**

191 We assessed the impact of RSPO certification on village well-being by comparing the change in equally-  
192 weighted indicators in villages with plantations certified for 5-11 years to those with non-certified plantations  
193 over the same time interval, while ensuring similar baseline characteristics in both types of villages  
194 (Supplementary Table 2). Results aggregated across the three Indonesian islands indicate that the impact of  
195 certification varied by baseline village primary livelihood sector prior to certification. Compared to similar  
196 villages with non-certified plantations, those with certified plantations experienced an overall reduction in well-  
197 being. Combined measures of socioeconomic and socioecological well-being declined by 11% on average in  
198 communities that relied on subsistence-based livelihoods prior to certification compared to non-certified  
199 villages (Figure 5b). This decline was driven mainly by the fall in socioecological indicators, predominantly via  
200 a significant increase in the prevalence of conflicts, low wage agricultural labourers, and water and air  
201 pollution (Extended Data Figure 6). Conversely, the overall well-being marginally improved by 4% in  
202 communities that relied on market-based livelihoods before certification (i.e. polyculture plantations or  
203 monoculture non-certified oil palm plantations) (Figure 5b).

204 We found that expansion of oil palm into new areas resulted in similar well-being change patterns as  
205 certification (Figure 5). Villages that relied on subsistence livelihoods prior to oil palm development  
206 experienced an overall reduction in well-being by 16% on average after 5-11 years compared to the  
207 counterfactual of no oil palm development across all three islands (Figure 5a). The reduction in overall well-  
208 being was driven by the decline in both socioeconomic and socioecological components, primarily the  
209 reduction in electricity access, adequate sanitation and cooking energy, and secondary schools, as well as  
210 the increased prevalence of conflicts, low wage agricultural labourers, water pollution, and floods (Extended  
211 Data Figure 7). Villages with oil palm plantations where the majority of communities had relied on market-  
212 based livelihoods before oil palm development (i.e. polyculture plantations outside concessions) also  
213 experienced reduced overall well-being by 9% compared to the counterfactual, but the impact on  
214 socioeconomic well-being was marginally positive (improved by 3% on average) (Figure 5a). Thus, the  
215 immediate impact of oil palm development in the production villages with market-based livelihoods appears to  
216 be better than that observed in villages dominated by subsistence-based livelihoods; socioecological losses  
217 appear to be partially compensated by socioeconomic gains.

218 Because in Kalimantan certification has taken place disproportionately in areas where village  
219 communities were still dependent on subsistence-based livelihoods (Figure 4a), the impact of certification on  
220 well-being in this region has been negative overall (Extended Data Figure 8b). On the other hand, the impact  
221 of certification in Sumatra has been positive overall (albeit marginal) (Extended Data Figure 8b), mitigating  
222 negative impacts on socioecological well-being indicators associated with non-certified oil palm. Unlike in  
223 Kalimantan, a higher proportion of plantations in Sumatra has been certified in villages where market-based  
224 communities are more dominant (Figure 4a). This demonstrates that failing to account for the influence of  
225 baseline livelihoods on the potential benefit flows of certification could lead to misplaced inferences from the  
226 impact evaluation.

## 227 **Well-being change through oil palm and certification processes**

228 Trends in the change of village well-being through the process of oil palm expansion and certification provide  
229 a more comprehensive picture of the underlying mechanisms driving the impact (Figure 6). In villages with  
230 subsistence livelihoods, socioeconomic improvements in oil palm villages were slightly slower to accumulate  
231 than those in non-oil palm villages, but this trend improved marginally following RSPO certification.  
232 Socioecological well-being in these subsistence-based villages worsened following oil palm development, a  
233 trend that continued after certification (Figure 6a). This pattern was widespread in Kalimantan (Extended Data

234 Figure 8b), particularly in lowland peatland areas near the coast, which have experienced most certification  
235 efforts to date. Conversely, improvements to socioeconomic well-being experienced in Indonesia were  
236 greater where oil palm, and later certification, was established in villages with market-based livelihoods.  
237 Measures of socioecological well-being in these market-based villages deteriorated following expansion of  
238 the oil palm sector, but later improved following certification, albeit marginally (Figure 6b). Thus,  
239 socioecological well-being in market-based villages with certification at the current state is indeed worse than  
240 without oil palm development two decades ago, but slightly better than the counterfactual of no certification a  
241 decade ago. This pattern is prevalent in Sumatra (Extended Data Figure 8b). Thus, focusing merely on the  
242 immediate effect of certification could lead to missed crucial information and insights about what happened in  
243 village communities before certification even existed.

244 The overall negative association between certification in subsistence-based villages and outcome  
245 variables (compared to a counterfactual of non-certified plantations) reflects not an adverse outcome from  
246 certification itself, but the overwhelming social impact of large-scale industrial oil palm plantations on the well-  
247 being of communities who still depend on forest and associated natural capital, which indeed may be difficult  
248 to compensate even within a sound regulatory certification framework. In Indonesia, the size of individual  
249 RSPO-certified plantations is significantly larger than non-certified industrial plantations (i.e. median  
250 plantations area of 8,000 and 2,500 ha for certified and non-certified plantations, respectively, based on data  
251 from Sumatra and Kalimantan) (Extended Data Figure 9a). A certified plantation company typically manages  
252 10% of village land areas across three adjoining villages (Extended Data Figure 9b). Comparatively, one non-  
253 certified industrial plantation company typically manages only 3% of a village land area (Extended Data  
254 Figure 9b). These differences are likely related to the high costs and technical capacities required for the  
255 RSPO membership participation and further for certification, which only large companies can bear<sup>45</sup>. This  
256 implies that there is likely an immense pressure being placed on the environment (i.e. soil, air, and water  
257 quality and quantity) by certified plantations and the associated mills relative to non-certified ones simply due  
258 to the total plantation size and production scale across broader landscapes comprising several neighbouring  
259 villages<sup>29,46,47</sup>. Further, the scale of certified plantations compared to the non-certified ones indicates that the  
260 certified companies tend to have a much larger influence over village land-use, environment, and economy  
261 compared to those managing non-certified plantations. This could create more unbalanced social power  
262 structures in certified plantations in which traditional communities and their local governance have a relatively  
263 limited say over what happens on their land<sup>40</sup>. Thus, although here we have carefully controlled for the total  
264 size of all industrial plantations at village-level in order to fairly compare certified versus non-certified

265 plantation villages (Supplementary Table 2), the effect observed in certified plantation villages is likely to be  
266 masked by the overall plantation impact over larger jurisdictional scales. This suggests that the amount of  
267 land under cultivation by a single entity has significant implications for the extent to which the perceived  
268 benefits of certification translate to improvements in community well-being. Our findings for the subsistence  
269 villages also imply that similar negative implications for community well-being recorded for certified  
270 plantations will likely occur for similarly extensive non-certified plantations.

## 271 Conclusion

272 The effectiveness of RSPO certification in upholding social and environmental standards within the oil palm  
273 industry has been called into question<sup>23,24</sup>. Using a comprehensive counterfactual assessment of longitudinal  
274 census data from Indonesia, the world's leading palm oil producing country, we show that the association  
275 between RSPO certification and village-level well-being varies by location and baseline village livelihood  
276 conditions before certification was initiated. While marginal positive impacts were observed in villages where  
277 most communities relied on market-based livelihoods prior to certification, RSPO certification was associated  
278 with largely negative outcomes in rural villages oriented toward subsistence agriculture. The latter was likely  
279 because certified plantations under single companies tend to be substantially larger than non-certified  
280 plantations and cover several neighbouring villages. As a result social and environmental externalities are  
281 difficult to remediate.

282 A potential caveat to these findings is that our analysis specifically focuses on the direct impact of  
283 certification and oil palm development on villages with oil palm production. We did not assess the possibility  
284 that impacts of oil palm or certification may be spatially autocorrelated or could lead to spillover effects<sup>29</sup> over  
285 a broader extent beyond the production areas, e.g. in neighbouring villages without the oil palm industry. If  
286 this kind of spill-over mechanism exists, the oil palm industry could even generate a wider welfare gap among  
287 villages at broader jurisdictional scales (e.g. regency level) by accruing socioeconomic and socioecological  
288 costs to rural subsistence-based villages with the oil palm industry while accumulating most of welfare  
289 benefits to suburban market-based villages. We also did not assess how different categories of oil palm  
290 production (i.e. different types of smallholders such as independent versus tied smallholders, and non-  
291 certified plantations) within villages classified as certified may have contributed to well-being, since data are  
292 not currently resolved to these levels. Our evaluation focuses on localised impacts collectively over large  
293 spatial scales but does not incorporate national-level socioeconomic benefits obtained through taxation of  
294 palm oil production. Additional indirect impacts of the RSPO on government sustainability policies and

295 practices for oil palm, such as the development of the national Indonesian Sustainable Palm Oil (ISPO)  
296 certification standard, are also so far immeasurable. These potential caveats notwithstanding, our appraisal  
297 has established important baseline information for further impacts to be monitored as the RSPO standard  
298 develops.

299 Our finding that oil palm development has failed to improve well-being in rural subsistence villages  
300 calls for careful consideration by key decision-makers of unintended indirect impacts of pushing large-scale  
301 industrial oil palm into frontier forest areas where local communities still rely heavily on environmental  
302 services. We feel that it is important for governments in oil palm producing countries to consider limiting the  
303 extent of industrial-scale plantations that can be developed until more positive impacts on community well-  
304 being can be guaranteed. This not only applies to existing rural areas in Indonesia, but also to other world  
305 regions such as Central and West Africa and Latin America where the oil palm industry is expanding. RSPO's  
306 recent commitment to zero-deforestation and avoidance of peatlands<sup>20</sup> as well as Indonesia's moratorium on  
307 concession allocation in primary forests and on peatlands should help steer the industry towards already  
308 developed agricultural lands with primarily market-based livelihoods.

309 Given that challenges associated with the oil palm industry vary by village baseline primary  
310 livelihoods, specific targeting of these livelihoods in certification criteria, as well as ensuring compliance with  
311 existing criteria with respect to livelihoods and communities, is recommended. In rural subsistence villages  
312 where industrial plantations have been established, we recommend further scrutiny by certification assessors  
313 on stringent compliance of social and environmental measures by companies - not only on zero deforestation,  
314 but also on preventing and mitigating pollution and water scarcity, and the avoidance of plantation expansion  
315 without Free, Prior and Informed Consent, as defined in the RSPO Principles and Criteria. In market-based  
316 villages, in addition to the aforementioned activities, the RSPO should continue focusing on supporting  
317 smallholder participation and encouraging company-smallholder cooperation. The RSPO jurisdictional  
318 approach to certification<sup>22</sup> has recently been piloted in several former transmigration villages, e.g. in Seruan  
319 Regency in Central Kalimantan, and holds great promise for these market-based villages in supporting  
320 "shared responsibilities" and cooperation across multiple stakeholders to work together towards improving  
321 sustainability at village jurisdictional levels.

322 **Methods**

323 **Data**

324 *Oil palm plantations and certification and land cover*

325 Throughout, the term 'plantation' refers to the area planted with oil palm, and 'concession' the area where a  
326 land permit has been granted to develop oil palm, but where the land has not necessarily been planted.  
327 Therefore, a concession owned by a company can either cover a larger area than the plantation if the  
328 concession is not fully developed, or cover roughly the same area as the plantation if the concession is  
329 entirely planted with palm. A plantation can also be developed outside a company concession, either as a  
330 smallholding or illegally<sup>43</sup>.

331 We used plantation maps of every three years between 1997 and 2014, described in Santika *et al.*  
332<sup>30,31</sup>, but extended to 2018 and to cover Sumatra and Papua. These include medium and large-scale  
333 industrial plantations (25-100 ha and >100 ha, respectively) and smallholder plots (<25 ha). We also used  
334 spatial data on oil palm concessions and RSPO member plantations (certified and non-certified) across  
335 Indonesia described in Carlson *et al.*<sup>26</sup>. The data contain concessions certified by 2015, which we updated to  
336 include those certified or proposed for certification between 2015 and 2018 through web searching of records  
337 of RSPO-certified mills and supply estates. Annual forest cover 2001-2018 was estimated by overlaying the  
338 extent of natural forest (primary and secondary) across Indonesia in 2000 provided by Margono *et al.*<sup>48</sup> and  
339 the locations of annual deforestation derived from the Global Forest Change (GFC) website<sup>49</sup>.

340 Combining information on forest cover, plantations, concession boundaries, and RSPO member  
341 plantations (certified and non-certified), we estimated the distributions of natural forest and three plantation  
342 ownership types (Figure 1): (1) RSPO-certified industrial plantations (CERT); (2) non-certified plantations  
343 within concession boundaries (which mainly includes the non-certified RSPO-member plantations and non-  
344 RSPO industrial-scale plantations) (CONC); (3) non-certified plantations outside concessions (largely  
345 includes independent smallholders (<25 ha) and small proportion of medium to large plantations ( $\geq 25$  ha) with  
346 unknown concession permit) (NCONC) (Supplementary Figure 1). Areas outside natural forest and oil palm  
347 plantations mainly comprise agricultural lands, mixed plantations (e.g. rubber, coffee), shrubs, settlements,  
348 and infrastructure (Figure 1). Our impact evaluation focussed specifically on oil palm plantations within  
349 concession boundaries (CONC) and RSPO-certified plantations (CERT), and excluded those outside known  
350 concession permits (NCONC). Detailed methodologies for generating these spatial data are provided in  
351 Supplementary Methods 3.

352 *Village primary livelihoods*

353 Primary livelihood sectors across the villages in Sumatra, Kalimantan and Papua were derived from the  
354 *Potensi Desa* (PODES) census, collected from village heads by the Central Bureau of Statistics (BPS) of  
355 Indonesia roughly every three years between 2000 and 2018<sup>37</sup>. These data contain information on the  
356 socioeconomic and development status for each village administrative boundary. Three major livelihoods  
357 were identified via PODES: (1) subsistence production including small-scale farming for staple foods, fishing,  
358 and the collection of forest products, (2) agricultural plantations including both polyculture and monoculture  
359 plantations, and (3) other sectors including horticulture, aquaculture, livestock, agricultural services, and non-  
360 agricultural activities (Figure 3a). In the analysis, market-based livelihoods includes agricultural plantations  
361 (polyculture and monoculture) and other sectors<sup>30,31</sup>.

362 *Indicators of well-being*

363 Village-level PODES data from 2000, 2003, 2005, 2008, 2011, 2014, and 2018 were used as proxy indicators  
364 for two aspects of village well-being, i.e. socioeconomic and socioecological (Santika *et al.* 2019a,b;  
365 Supplementary Table 1). The socioeconomic aspect includes living conditions, infrastructure, and income  
366 support, and the socioecological aspect includes security, social equity, and natural hazard prevention<sup>50,51</sup>.  
367 PODES provides the most comprehensive public information on land-use, population demographics, and  
368 village infrastructure available in Indonesia, and has been used extensively to inform government policy and  
369 development studies<sup>52,53</sup>. The choice of indicators and directionality of the effects on well-being listed in  
370 Supplementary Table 1 correspond to existing methodologies used to assess poverty and livelihoods<sup>30,31</sup>,  
371 such as the Sustainable Livelihood Approach (SLA<sup>34</sup>), the Multidimensional Poverty Index (MPI<sup>54</sup>), and the  
372 Nested Spheres of Poverty (NESP<sup>55</sup>). Our categorization of indicators closely follows that advocated by the  
373 SLA<sup>34,35</sup>, in which the socioeconomic grouping encapsulates the human (basic), physical, and financial  
374 dimensions of well-being, and the socioecological encapsulates social and natural dimensions  
375 (Supplementary Methods 2).

376 **Analysis of land-use and livelihood change at village level**

377 To capture the patterns of transition in primary land-use towards RSPO-certified plantations at village level,  
378 we classified each village into one of four categories based on the dominant land cover: (1) natural forest; (2)  
379 agricultural lands, mixed plantations and shrubs; (3) non-certified industrial oil palm plantations; and (4)  
380 RSPO-certified industrial oil palm plantations. Following a classification tree (Supplementary Figure 3), we  
381 first sorted villages based on the percentage of natural forest cover (primary and secondary forest): (1)

382 villages with  $\geq 50\%$  of the land area allocated to natural forest (hereafter termed as 'villages with primarily  
383 natural forest'); and (2) the remaining villages ( $>50\%$  of the land areas allocated to agriculture, plantations,  
384 shrubs and other land-uses). We then divided the second category based on the extent of industrial-scale  
385 plantations: (1) villages with  $\geq 10\%$  of the land area allocated to planted industrial oil palm concession  
386 (hereafter termed as 'oil palm plantation villages'); and (2) those otherwise (hereafter termed as 'villages with  
387 primarily agricultural lands, mixed plantations, and shrubs'). Finally, we divided the 'oil palm villages' based  
388 on the extent of certified plantations: (1) villages with  $\geq 10\%$  of the land area allocated to planted certified oil  
389 palm concession (hereafter termed as 'RSPO-certified plantation villages'); and (2) those otherwise  
390 (hereafter termed as 'Non-certified plantation villages'). We used the 10% threshold for defining the oil palm  
391 plantations based on the median proportion of village land area allocated to industrial oil palm  
392 plantations across Sumatra, Kalimantan and Papua (Supplementary Figure 4c, left plot). We also used the  
393 10% threshold for defining RSPO-certified plantation villages for the same reason across Sumatra and  
394 Kalimantan, noting there were insufficient certified plantations in Papua to evaluate impact there  
395 (Supplementary Figure 4d).

396 We tracked the change in village primary land-use that leads to predominantly industrial-scale oil  
397 palm plantations and RSPO certification between 2000 and 2018 across villages in Sumatra, Kalimantan and  
398 Papua (see Supplementary Table 3 for the number of villages for assessed). To obtain an approximation of  
399 the latent structure of land-use change, we used the observed village primary land-use in 2000, 2005, 2011,  
400 and 2018 (Supplementary Figure 3).

401 To determine the livelihood dynamics associated with land-use change, we quantified the likelihood  
402 of a village falling within the three livelihood classes (i.e. subsistence livelihoods; agricultural plantations; and  
403 other sectors) for each primary land-use category (i.e. natural forest; agricultural lands, mixed plantations and  
404 shrubs; non-certified industrial oil palm plantations; and RSPO-certified industrial oil palm plantations) in  
405 2000, 2005, 2011 and 2018 (Figure 3a). To provide a nuanced understanding of the scale of plantations  
406 (either small to medium landholders, or large-scale industrial plantations) associated with each livelihood  
407 class, we calculated the average proportion of village plantations located within the boundaries of oil palm  
408 concession. Larger proportions indicate a higher likelihood of the primary livelihood sector and economy in a  
409 village being driven by large-scale monoculture oil palm plantations compared to small and medium-scale  
410 plantations (Figure 3a). To assess the change in community composition and migration in the village, we also  
411 quantified the likelihood of each village falling within three broad ethnic identities or classes (i.e. all people  
412 identify as belonging to ethnic groups native to the island in question; majority belong to ethnic groups native

413 to the island; or majority belong to ethnic groups from outside the island) for each village primary land-use  
414 category over the same period (Figure 3b).

## 415 **Analysis of impact evaluation**

### 416 *Spatial and temporal unit of analysis*

417 We conducted two separate impact evaluation analyses on poverty: (A) the impact of industrial oil palm  
418 plantations, and (B) impact of RSPO certification. For both analyses, we used the village administrative  
419 boundary as the spatial unit of analysis, which was defined in the BPS census in 2014<sup>56</sup>. The impact of oil  
420 palm on the change in village well-being (analysis A) was determined 5-11 years after plantation development  
421 to allow for time delays in the accrual of well-being benefits, e.g. profits from harvesting<sup>57</sup> and infrastructure  
422 development<sup>58</sup>, as well as manifestation of social and environmental impacts, e.g. conflicts<sup>7,9</sup>, influx of  
423 workers<sup>5</sup>, and pollution<sup>12</sup>. The impact of certification on the change in village well-being (analysis B) was also  
424 determined 5-11 years after certification. To do so, we compared the change in indicators between paired  
425 PODES censuses, i.e. 2000 and 2005 (5 years), 2000 and 2008 (8 years), 2000 and 2011 (11 years). The oil  
426 palm impact analysis covered 11 paired census data, and the analysis of certification impact covered three  
427 (Supplementary Table 4).

### 428 *Units for treatment and counterfactual (control)*

429 When evaluating the impact of industrial oil palm plantation development (analysis A), the units receiving  
430 treatment were villages with  $\geq 10\%$  of their land area allocated to industrial oil palm plantation over the full  
431 study periods, but not within the previous five years. We used the 10% threshold based on the approximate  
432 median proportion of village land area allocated to industrial oil palm plantations across Sumatra, Kalimantan  
433 and Papua (Supplementary Figure 4c, left plot). As the unit for counterfactuals or controls, we used villages  
434 where none of the land areas were allocated to industrial oil palm plantations over the range of the analysis  
435 period, nor in the five years prior to that (see conceptual diagram outlining the definitions in Supplementary  
436 Figure 5).

437 For the certification impact analysis (analysis B), the units receiving treatment were oil palm villages  
438 (i.e. villages with  $\geq 10\%$  of the land areas allocated to industrial oil palm plantations) where  $\geq 10\%$  of the land  
439 area were assigned to certified plantations over the full analysis periods, but no certified plantations were

440 detected within the previous three years. Again the 10% threshold for certification was based on the  
441 approximate median proportion of village land area allocated to certified plantations across Sumatra and  
442 Kalimantan (excluding Papua as few plantations were certified) (Supplementary Figure 4d). For the  
443 counterfactual, we used oil palm villages with the same proportion of their areas allocated to industrial oil  
444 palm plantations as that in the treated villages and where none of the plantations were certified over the  
445 analysis period, nor in the previous three years (Supplementary Figure 6).

446 *Analytical framework*

447 For each of two impact evaluations (oil palm and certification, separately) we followed four steps. First, for  
448 each island and time period (or paired PODES censuses) we generated the propensity score or likelihood for  
449 the spatial assignment of industrial oil palm plantations or certification based on a given set of biophysical and  
450 socioeconomic variables. Second, we applied a binary matching method for each island and time period to  
451 select control villages with similar baseline characteristics as those in the treated villages through nearest  
452 neighbour matching or search of propensity score and exact matching of key categorical variables. Third, we  
453 applied difference-in-difference regression to the matched dataset. Fourth, we conducted diagnostic tests and  
454 sensitivity analyses to verify the robustness of our estimates against modelling specification and approach.  
455 Detailed steps for conducting each impact evaluation are provided in Supplementary Methods 4.

456 **Step 1: Generating propensity scores**

457 We generated the propensity scores for each island (i.e. Sumatra, Kalimantan and Papua for analysis A;  
458 Sumatra and Kalimantan for analysis B) and time period by employing a non-parametric generalized boosted  
459 regression model (GBM) for binary outcomes implemented in the R-package gbm<sup>59</sup>. The GBM model allows  
460 flexibility in fitting non-linear response curves for predicting treatment assignment and can incorporate a large  
461 number of covariates without negatively affecting model prediction. We controlled for potentially confounding  
462 variables in each impact assessment in terms of both selections of villages for treatment and the outcome  
463 being measured (Supplementary Table 2). To achieve this, we included variables representing: (a) socio-  
464 political factors, (b) accessibility, (c) agricultural productivity, and (d) baseline village socioeconomic  
465 conditions. This selection is based on previous analyses of oil palm expansion without certification in  
466 Kalimantan<sup>30,31</sup>.

467 **Step 2: Applying the matching method**

468 For analysis A, we employed a binary matching method<sup>60</sup> to select a set of control villages in which oil palm  
469 plantations had not been developed and that exhibited the same baseline characteristics as villages where  
470 plantations had been established. For analysis B, we applied the matching to select a set of control oil palm  
471 villages without certification and which exhibited the same baseline characteristics as oil palm villages where  
472 certification had been granted. Both analyses A and B were performed based on nearest-neighbour matching  
473 of propensity scores using all variables described in Supplementary Table 2 and exact matching of the  
474 categorical baseline variables (i.e. *KBPT*, *LZON*, *FORB*, *SOIL*, and *LVHD*). We applied a 0.25 calliper width  
475 of each propensity score standard deviation in the nearest neighbour approach, as this width was previously  
476 shown to be optimal<sup>61</sup>. Matching algorithms were implemented separately for each of the 18 indicators of  
477 well-being (Supplementary Table 1) in the R-package Matching<sup>62</sup>.

478 For analysis A, the matching method was applied for each of the indicators (Supplementary Table 1),  
479 three islands (Sumatra, Kalimantan, and Papua), and 11 time periods (Supplementary Table 4), separately.  
480 We observed substantial improvement in the extent of overlapping areas of all continuous variables (*ELEV*,  
481 *SLOP*, *CITY*, *POPB*, *SDRY*, *SWET*, *TRNS*, and *VILA*) between villages with and without industrial oil palm  
482 plantation development in the matched dataset compared to the original (unmatched) dataset  
483 (Supplementary Figure 7 and Supplementary Table 5; aggregated across 18 indicators of well-being, three  
484 islands, and 11 time periods). For analysis B, the matching method was applied for each indicator  
485 (Supplementary Table 1), two islands (Sumatra and Kalimantan), and three time periods (Supplementary  
486 Table 4), separately. Again, we observed substantial improvement in the extent of overlapping areas of all  
487 continuous variables (*ELEV*, *SLOP*, *CITY*, *POPB*, *SDRY*, *SWET*, *TRNS*, *VILA*, and *OPV*) in the oil palm  
488 villages with and without certification after matching was performed (Supplementary Figure 8 and  
489 Supplementary Table 6; aggregated across 18 indicators of well-being, two islands, and three time periods).

#### 490 **Step 3: Difference-in-difference regression**

491 For each indicator of well-being  $k$ , we first calculated the change or difference over 5–11 years (i.e. between  
492 two PODES censuses), and then multiplied the change by  $w_k$  (Supplementary Table 1). The value of  $w_k$   
493 represents the directional effect of the change in indicator  $k$  that defines improvement in well-being, i.e.  $w_k=1$   
494 if positive change (or an increase) in indicator  $k$  represents improvement in well-being (e.g. proportion of  
495 household with electricity) and  $w_k= -1$  if negative change (or a reduction) in indicator  $k$  represents  
496 improvement in well-being (e.g. prevalence of malnutrition, frequency of conflicts). We then divided the value  
497 by the maximum of the absolute change of well-being across all villages and time periods within each island.  
498 Thus, we obtained values that ranged roughly between -1 and 1, where -1 and 1 denote the largest reduction

499 and improvement in the well-being indicator across all study villages in each island, respectively, and 0  
500 denotes no change in the well-being indicator after 5-11 years. We applied this transformation approach  
501 mainly to preserve information about the directionality of change in well-being (i.e. relative improvement or  
502 reduction) over time, and to allow comparable measures across different indicators.

503 The impact of industrial oil palm plantations (analysis A) on village-level well-being was estimated by  
504 comparing the change in well-being indicators in villages with oil palm plantation development with the  
505 change in control villages without plantations, i.e. the difference in the differences in well-being indicators  
506 between two PODES censuses between oil palm and non oil palm villages, for each island and village  
507 livelihood type. The impact of oil palm certification (analysis B) on village-level well-being was estimated by  
508 comparing the change in well-being indicators in oil palm villages with certified plantations with the change in  
509 control oil palm villages without certification, i.e. the difference in the differences in well-being indicators  
510 between two PODES censuses between certified and non certified oil palm villages, for each island and  
511 village livelihood type. The number of villages assessed for both analyses is shown in Supplementary Table  
512 3. The overall effect (and confidence interval) of industrial oil palm plantations or RSPO certification on  
513 improving each aspect of well-being for each island and livelihood type was obtained by pooling estimates  
514 across all indicators belonging to the same group of well-being aspect (Supplementary Table 1).

#### 515 **Step 4: Diagnostic tests and sensitivity analyses**

516 To assess the quality of our matched dataset we examined the change in the distributions of variables  
517 potentially affecting the assignments of industrial oil palm plantation villages (for analysis A) or certified  
518 plantation villages (for analysis B) before and after matching procedure. We achieved bias reduction of 92.9-  
519 98.6% for covariates matched in analysis A (Supplementary Table 5), and 81.7-98.3% for analysis B  
520 (Supplementary Table 6), indicating that samples were strongly matched in both assessments.

521 We conducted a series of sensitivity analyses to verify the robustness of our estimates against  
522 modelling specification and approach. This included: (1) generating propensity scores separately within  
523 island, time period, and livelihood type, in contrast to our main approach of generating the scores within  
524 island and time period; and (2) applying different categorization of well-being indicators by shifting indicators  
525 security and social equity from socioecological to socioeconomic aspects. The alternative method for  
526 generating the propensity scores yielded similar conclusions about the impact of oil palm development  
527 (analysis A) and certification (analysis B) on well-being as those generated by the main approach  
528 (Supplementary Figure 9). The alternative grouping of indicators under the socioeconomic and

529 socioecological aspects resulted in worsened performance of industrial oil palm development (analysis A) and  
530 certification (analysis B) on village well-being than those obtained from the main approach (Supplementary  
531 Figure 10). This is because the negative impact of oil palm development or certification on key indicators of  
532 social well-being (i.e. prevalence of conflicts and low wage agricultural labourers) tended to be less  
533 pronounced than the negative impact on natural hazard prevalence, but worse than the impact on living  
534 conditions, infrastructure provision, and income support (Extended Data Figures 6-7).

535 **Data availability**

536 Key datasets used to conduct our analysis are publicly available from the cited references (forest cover data  
537 available from <https://glad.umd.edu/dataset/primary-forest-cover-loss-indonesia-2000-2012> and  
538 [https://earthenginepartners.appspot.com/science-2013-global-forest/download\\_v1.5.html](https://earthenginepartners.appspot.com/science-2013-global-forest/download_v1.5.html) and socioeconomic  
539 data from <https://mikrodata.bps.go.id/mikrodata/index.php/catalog/PODES>).

688 **Figure captions**

689 **Figure 1. Change in distribution of forest and oil palm plantations in Sumatra, Kalimantan and Papua.**

690 The change in the distribution of forest and oil palm plantations every 9 years between 2000 and 2018 across  
691 three major Indonesian islands: (a) Sumatra, (b) Kalimantan, and (c) Papua. Oil palm plantations are grouped  
692 into three categories: (1) RSPO-certified plantations, i.e. certified large-scale industrial plantations (CERT),  
693 (2) non-certified plantations within oil palm concessions, i.e. non RSPO-certified large-scale industrial  
694 plantations (CONC), and (3) non-certified plantations outside known oil palm concessions, i.e. mainly  
695 independent small-scale landholders and medium to large-scale plantations with unknown concession status  
696 (NCONC) (see Methods). Detailed maps for portions of each island are provided in Extended Data Figures 2-  
697 4.

698 **Figure 2. Village land-use (and associated livelihood) pathways to oil palm certification.** (a) The

699 change in village primary land-use, from (1) high natural forest cover to (2) agricultural lands, mixed  
700 plantations and shrubs, followed by (3) industrial oil palm plantations (non-certified), then finally becoming (4)  
701 RSPO-certified industrial plantations. (b) The change in village primary livelihoods and community  
702 composition most likely associated with the change in village primary land-use, from (1) subsistence-based  
703 livelihoods in complex agroforestry systems (weak market exposure) dominated by indigenous communities,  
704 to (2) polyculture plantation (smallholding) livelihoods (moderate market exposure) dominated by indigenous  
705 communities and a higher proportion of migrants, then finally becoming (3) monoculture oil palm plantation  
706 livelihoods (stronger market-driven) with a high proportion of migrants.

707 **Figure 3. Village primary livelihoods and ethnic features or identities by village primary land-use.** (a)

708 Proportion of villages with primary livelihoods subsistence-based, agricultural plantations, and other sectors,  
709 and proportion of village land area allocated to natural forest, polyculture plantations, monoculture  
710 plantations, and other land-uses for each livelihood class, by village primary land-use (natural forest;  
711 agricultural lands, plantations, and shrubs; non-certified industrial oil palm plantations; and RSPO-certified  
712 industrial oil palm plantations), averaged across 2000, 2005, 2011 and 2018 data. (b) Proportion of villages  
713 within each land-use type that are composed of people who all, or mostly identify themselves belonging to  
714 ethnic groups native, versus non-native, to the island.

715 **Figure 4. Village land-use (and the associated livelihood) change matrix to oil palm plantation and**

716 **certification.** (a) Change in village primary land-use (and the associated primary livelihoods) between 2000

717 and 2018, from natural forest; agricultural lands, mixed plantations and shrubs; and non-certified industrial oil  
718 palm plantations in 2000; to non-certified industrial oil palm plantations and RSPO-certified plantations in  
719 2018, in Sumatra, Kalimantan, and Papua. (b) Schematic diagram of transition of village primary land-use  
720 (and the associated livelihoods) between 2000 and 2018 from left to right, representing different development  
721 stages of the industrial oil palm plantations for Papua, Kalimantan, and Sumatra, i.e. early, intermediate, and  
722 advanced stage, respectively. The boxes in Figure 4b represent the development stage of the island, not  
723 necessarily the parts where oil palm expanded. We used 6 villages in each box to best resemble the matrix  
724 described in Figure 4a.

725 **Figure 5. Impact of oil palm plantation development and certification on well-being in oil palm-  
726 growing villages.** (a) Impact of oil palm plantations on village-level well-being, evaluated by comparing the  
727 change in well-being indicators in villages with oil palm after 5-11 years of plantation development against the  
728 change in well-being in villages without oil palm across Sumatra, Kalimantan and Papua. (b) Impact of RSPO  
729 certification on village-level well-being, evaluated by comparing the change in well-being indicators in villages  
730 with certified plantation after 5-11 years of certification against the change in well-being in villages with non-  
731 certified oil palm plantations across Sumatra and Kalimantan. In both analyses comparisons are made  
732 between village types with similar baseline characteristics appropriate to the datasets analysed. N represents  
733 the number of villages assessed in each panel. Error bars represent 95% confidence intervals of combination  
734 of all indicators in the groups.

735 **Figure 6. Trends in the change of village well-being through the oil palm and certification processes.**  
736 Trends in the change of socioeconomic and socioecological well-being indices within 5-11 years (median 8  
737 years) before and after oil palm development, and within 5-11 years (median 8 years) after oil palm  
738 certification. Villages are partitioned by their baseline primary livelihoods (a) subsistence-based livelihoods  
739 typical of the majority of plantations in Kalimantan, or (b) market-based livelihoods typical of most villages  
740 with oil palm in Sumatra and Papua. N represents the number of villages assessed in each panel. Error bars  
741 represent 95% confidence intervals. It is worth noting that the baseline characteristics of samples for  
742 generating the left (Non-OP → OP) and right (OP → Cert) panels are different, thus the counterfactual  
743 comparisons should only be made within panels. The estimates in T-8 time period are the same between the  
744 treated and control villages because the samples were matched.

745 **Extended Data Figure captions**

746 **Extended Data Figure 1. Total plantation area for key agricultural commodities across Indonesia and**  
747 **types of ownerships.** (a) Bar chart representing the total plantation area in 2019 for key agricultural  
748 commodities across Indonesia, and pie chart (above the bar) representing the proportion of different type of  
749 producer for each commodity, including smallholders, state or public-run companies, and private companies.  
750 (b) The change in cultivation area of the top five commodities (oil palm, rubber, coconut, cocoa, and coffee)  
751 every five years between 1980 and 2019, by producer type. Data were obtained from the Directorate General  
752 of Estate Crops Indonesia (2019).

753 **Extended Data Figure 2. Detailed change in distribution of forest and oil palm plantations in Sumatra.**  
754 Detailed change in the distribution of natural forest and oil palm plantations every 9 years between 2000 and  
755 2018 in three major oil palm regions in Sumatra. Oil palm plantations are grouped into three categories: (1)  
756 RSPO-certified plantations (CERT), (2) non-certified plantations within oil palm concessions (CONC), and (3)  
757 non-certified plantations outside known oil palm concessions (NCONC).

758 **Extended Data Figure 3. Detailed change in distribution of forest and oil palm plantations in**  
759 **Kalimantan.** Detailed change in the distribution of natural forest and oil palm plantations every 9 years  
760 between 2000 and 2018 in four oil palm regions in Kalimantan. Oil palm plantations are grouped into three  
761 categories: (1) RSPO-certified plantations (CERT), (2) non-certified plantations within oil palm concessions  
762 (CONC), and (3) non-certified plantations outside known oil palm concessions (NCONC).

763 **Extended Data Figure 4. Detailed change in distribution of forest and oil palm plantations in Papua.**  
764 Detailed change in the distribution of natural forest and oil palm plantations every 9 years between 2000 and  
765 2018 in three oil palm regions in Papua. Oil palm plantations are grouped into three categories: (1) RSPO-  
766 certified plantations (CERT), (2) non-certified plantations within oil palm concessions (CONC), and (3) non-  
767 certified plantations outside known oil palm concessions (NCONC).

768 **Extended Data Figure 5. Latent and observed change in village primary land use (and the associated**  
769 **livelihoods) to oil palm certification.** (a) Latent change in village primary land use (and the associated  
770 livelihoods), from high natural forest cover, to agricultural lands, mixed plantations and shrubs, followed by  
771 industrial oil palm plantations (non-certified), then finally becoming RSPO-certified industrial plantations. (b)  
772 Observed change in village primary land use (and the associated livelihoods) to industrial oil palm plantations

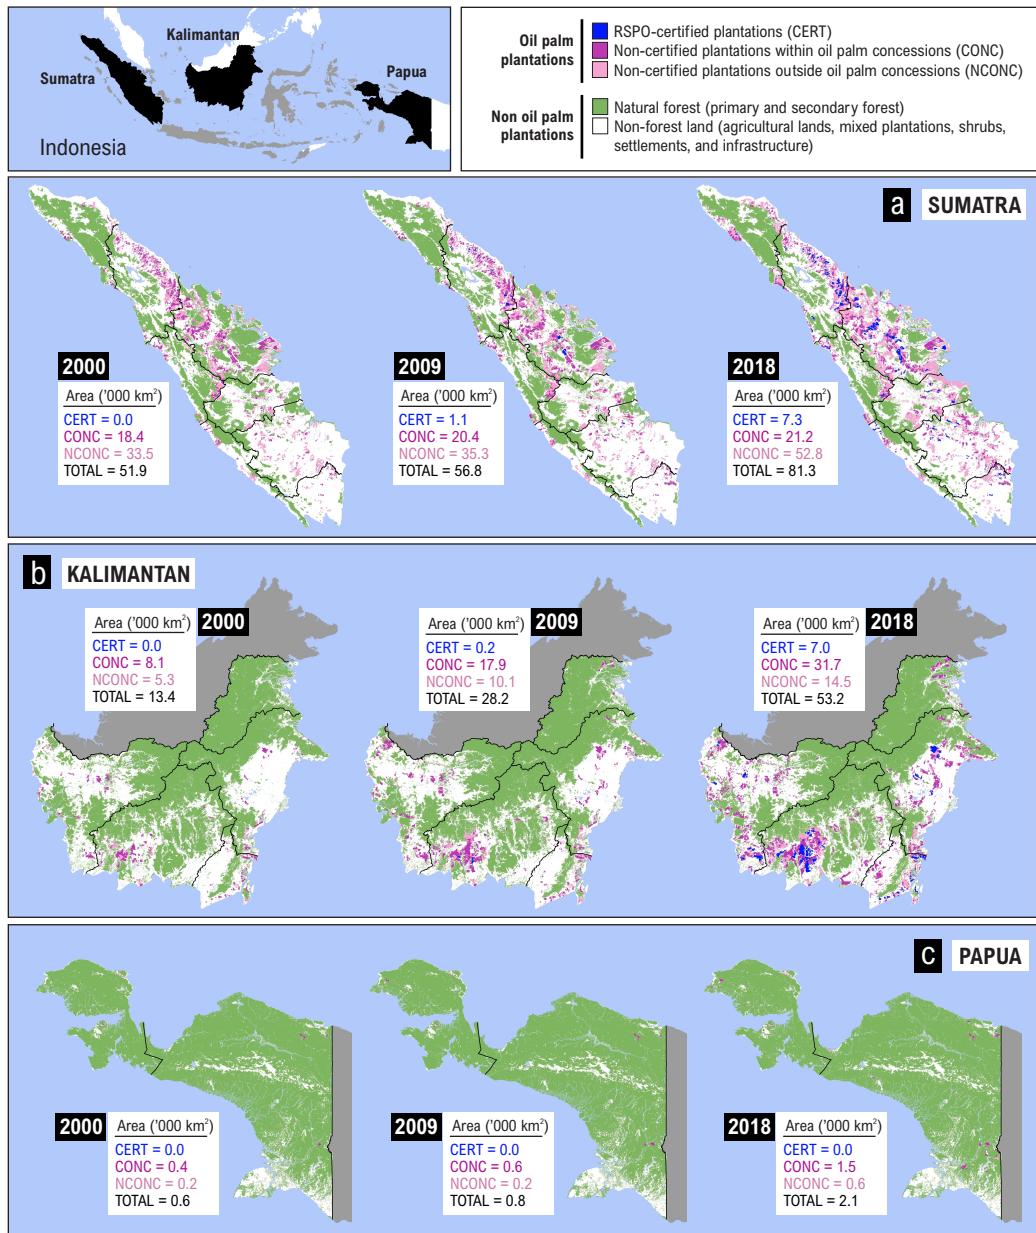

773 and certification based on land cover data and PODES censuses 2000, 2005, 2011, and 2018 (see Methods),  
774 aggregated across Sumatra, Kalimantan, and Papua. Percentage on the right hand side of each row  
775 represents the proportion of villages with the associated transition between 2000 and 2018.

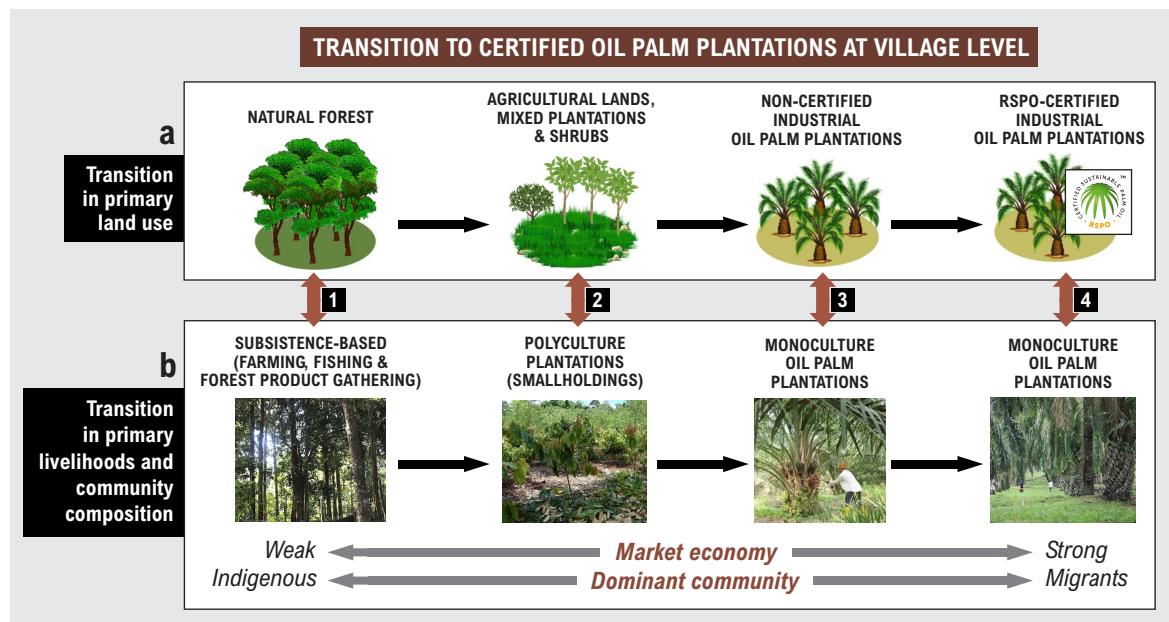

776 **Extended Data Figure 6. Impacts of RSPO-certification on indicators of well-being by village primary**  
777 **livelihoods.** The impact of oil palm certification (transition from oil palm villages to certified plantation  
778 villages) on each indicator of well-being in villages with primary livelihoods: (a) subsistence production, and  
779 (b) market-based. Indicators of well-being were grouped to socioeconomic and socioecological dimensions.  
780 Socioeconomic indicators include housing conditions (POOR), access to electricity (ELCT), cooking fuel  
781 (COOK), and toilet facilities (TOLT), child malnutrition incidence (MLNT), distance to healthcare facility  
782 (HEAL), primary school (PSCH), and secondary school (SSCH), and access to cooperative scheme (COOP)  
783 and credit facilities (CRDT). Socioecological indicators include the prevalence of conflicts (CNFL), agricultural  
784 labourers (AGLB), small industries (SIND), suicidal rates (SUIC), voluntary cleaning and maintenance  
785 (GTRY), water pollution (WPOL), air pollution (APOL), and floods and landslides (FLOD). Results were  
786 derived across 3 time periods and two islands (Sumatra and Kalimantan). N represents the number of  
787 villages used to derive the impact estimates for each well-being indicator. Error bars represent 95%  
788 confidence intervals. See Supplementary Table 1 for description of each well-being indicator.

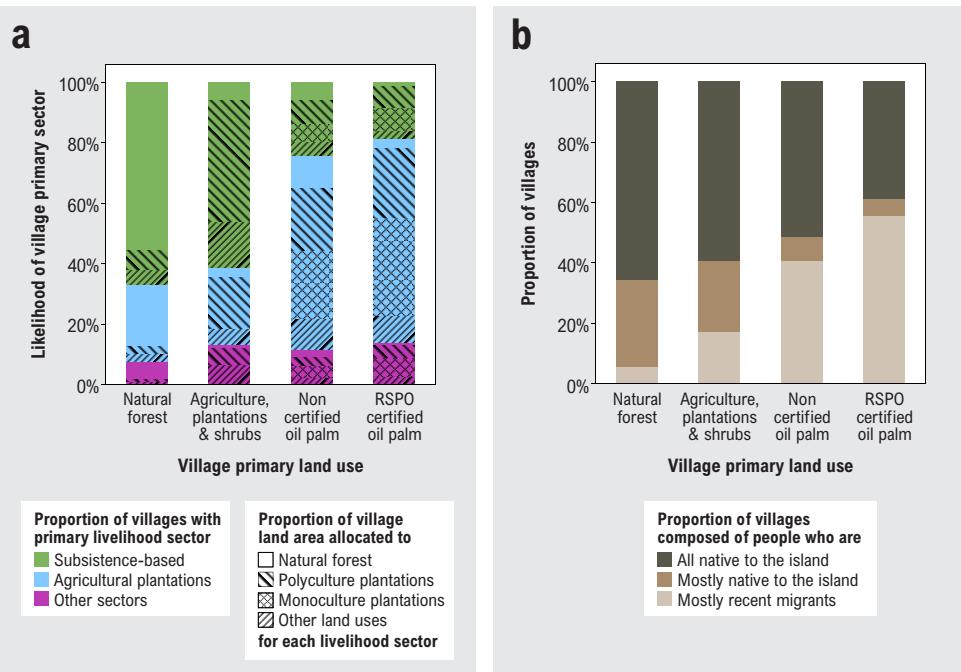

789 **Extended Data Figure 7. Impacts of industrial oil palm plantation development on indicators of well-**  
790 **being by village primary livelihoods.** The impact of industrial oil palm plantation development (transition  
791 from non oil palm villages to oil palm villages) on each indicator of well-being in villages with primary  
792 livelihoods: (a) subsistence production, and (b) market-based. Indicators of well-being were grouped to  
793 socioeconomic and socioecological dimensions. Socioeconomic indicators include housing conditions  
794 (POOR), access to electricity (ELCT), cooking fuel (COOK), and toilet facilities (TOLT), child malnutrition  
795 incidence (MLNT), distance to healthcare facility (HEAL), primary school (PSCH), and secondary school  
796 (SSCH), and access to cooperative scheme (COOP) and credit facilities (CRDT). Socioecological indicators  
797 include the prevalence of conflicts (CNFL), agricultural labourers (AGLB), small industries (SIND), suicidal  
798 rates (SUIC), voluntary cleaning and maintenance (GTRY), water pollution (WPOL), air pollution (APOL), and  
799 floods and landslides (FLOD). Results were derived across 11 time periods and three islands (Sumatra,  
800 Kalimantan, and Papua). N represents the number of villages used to derive the impact estimates for each  
801 well-being indicator. Error bars represent 95% confidence intervals. See Supplementary Table 1 for  
802 description of each well-being indicator.

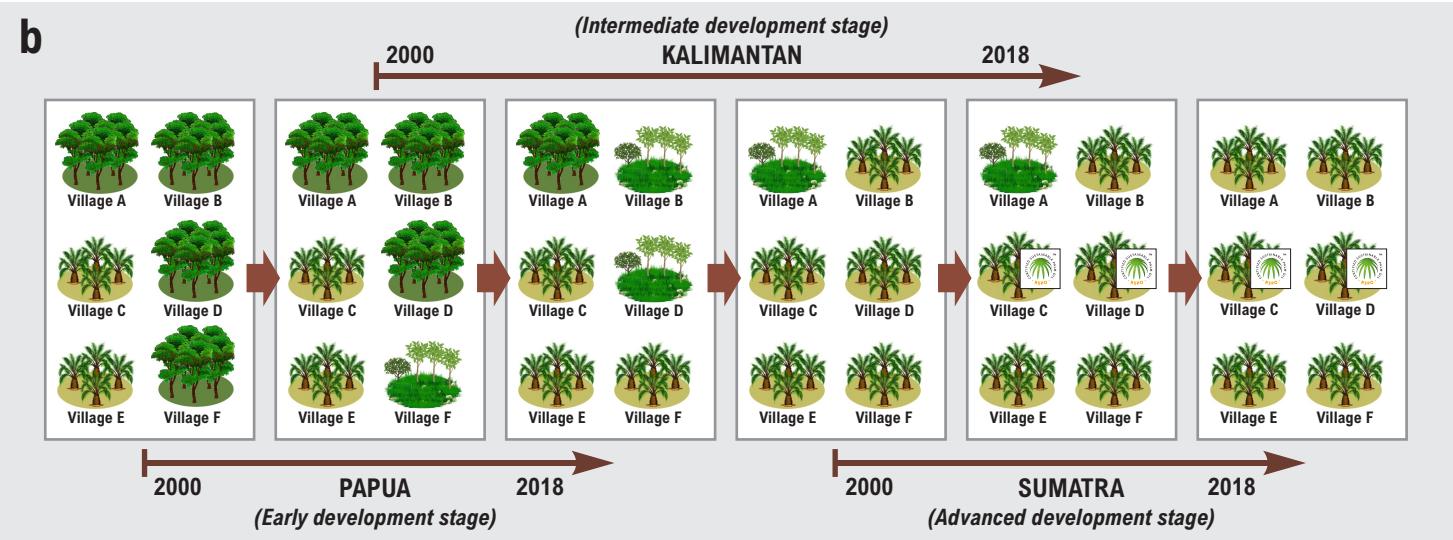

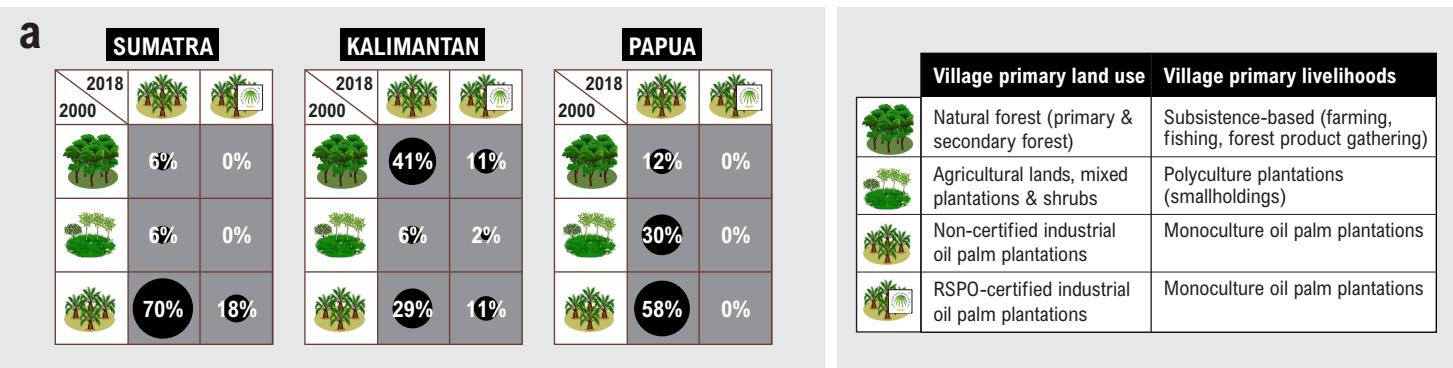

803 **Extended Data Figure 8. Impact of oil palm plantation development and certification on well-being in**  
804 **oil palm growing villages by island.** (a) Impact of oil palm plantations on village well-being in Sumatra,  
805 Kalimantan, and Papua, evaluated by comparing the change in well-being indicators in villages 5-11 years  
806 after industrial oil palm plantation development against the change in well-being in villages without industrial  
807 oil palm plantation, while ensuring similar baseline characteristics in both types of villages. (b) Impact of  
808 RSPO certification on village well-being in Sumatra and Kalimantan, evaluated by comparing the change in  
809 well-being indicators in villages 5-11 years after certification against the change in well-being in villages with  
810 non-certified industrial oil palm plantations, while ensuring similar baseline characteristics in both types of  
811 villages. N represents the number of villages assessed in each panel. Error bars represent 95% confidence  
812 intervals.

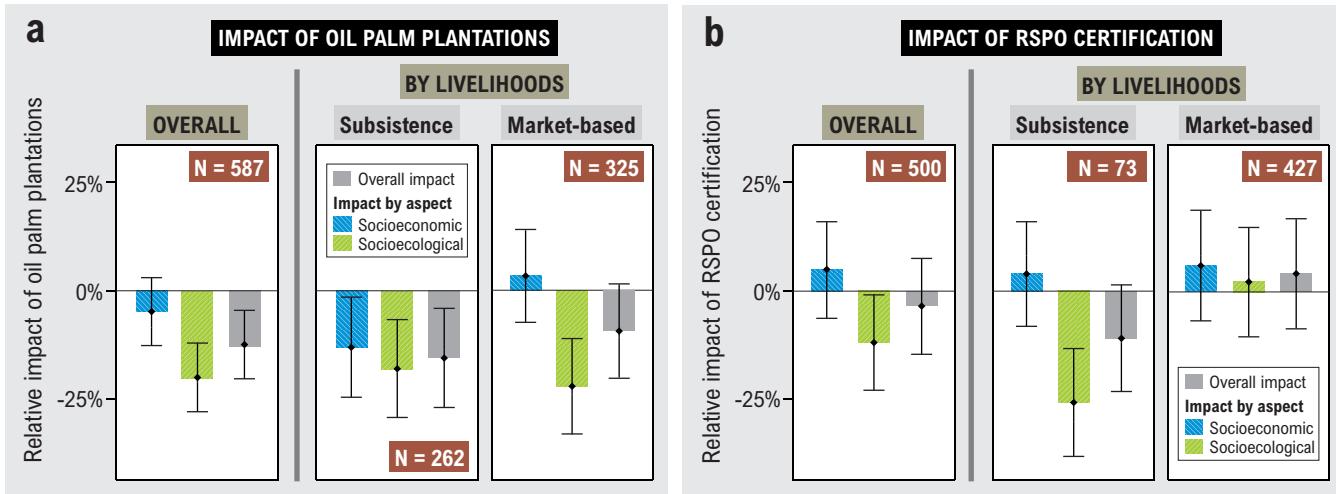

813 **Extended Data Figure 9. Size of individual industrial oil palm plantation and number of villages**  
814 **covered by one plantation, by certification status.** (a) Size of each large-scale plantation by certification  
815 status in the islands of Sumatra, Kalimantan, and Papua. (b) Number of villages covered by each large-scale  
816 industrial plantation and the proportion of village land area allocated to each plantation, by certification status.  
817 Plantation certification status includes (1) RSPO-certified plantations, i.e. certified large-scale industrial  
818 plantations (CERT) and (2) non-certified plantations within oil palm concession boundaries, i.e. non-certified  
819 large-scale industrial plantations (CONC).
